

Package ‘FatTailsR’

April 21, 2025

Title Kiener Distributions and Fat Tails in Finance and Neuroscience

Description Kiener distributions K1, K2, K3, K4 and K7 to characterize distributions with left and right, symmetric or asymmetric fat tails in finance, neuroscience and other disciplines. Two algorithms to estimate the distribution parameters, quantiles, value-at-risk and expected shortfall. IMPORTANT: Standardization has been changed in versions $\geq 2.0.0$ to get $sd = 1$ when $kappa = Inf$ rather than $2 * pi / sqrt(3)$ in versions $\leq 1.8.6$. This affects parameter g (other parameters stay unchanged). Do not update if you need consistent comparisons with previous results for the g parameter.

Version 2.0.0

Date 2025-04-21

Depends R ($\geq 4.1.0$)

Imports minpack.lm, timeSeries, parallel, methods, stats

Suggests zoo, xts

FatTailsR-package	<i>Package FatTailsR</i>
-------------------	--------------------------

Description

This package includes Kiener distributions K1, K2, K3, K4 and K7 and two estimation algorithms to characterize with a high precision symmetric or asymmetric distributions with left and right fat tails that appear in market finance, neuroscience and many other disciplines. The estimation of the distribution parameters, quantiles, value-at-risk and expected shortfall is usually very accurate. Two datasets are provided, as well as power hyperbolas and power hyperbolic functions which are simplified versions of symmetric distribution K1.

Download the pdf cited in the references to get an overview of the theoretical part and several examples on stocks and indices.

A commercial package, `FatTailsRplot`, with advanced plotting functions and calculation of matrix of stocks over rolling windows is also developed by the author.

IMPORTANT: A breaking change has been introduced in version 2.0.0 in order to get asymptotic values consistent with the standardized logistic distribution, i.e. $sd = 1$ when $kappa = Inf$. The scaling parameter g is now combined with the fixed value $g*\sqrt{3}/\pi$ and replace $g/2$. Other parameters stay unchanged. Do not update if you need consistent comparisons with versions $\leq 1.8.6$ for the g parameter. Do not mix results with versions $\leq 1.8.6$ and versions $\geq 2.0.0$.

Details

With so many functions, this package could look fat. But it's not! It's rather agile and easy to use! The various functions included in this package can be assigned to the following groups:

1. Two datasets presented in different formats: list, data.frame, matrix, timeSeries, xts, zoo:
 - `getDSdata`.
 - `extractData`, `dfData`, `mData`, `tData`, `xData`, `zData`.
2. Functions to calculate (positive, negative) prices to returns on vector, matrix, array, list, data.frame, timeSeries, xts, zoo:
 - `elevate`.
 - `fatreturns`, `logreturns`.
3. Several predefined vectors of probability. One function to check them. A conversion function from probabilities to characters
 - `pprobs0`, `pprobs1`, `pprobs2`, ..., `pprobs9`.
 - `checkquantiles`.
 - `getnamesk`.
4. Miscellaneous functions related to the logistic function:
 - `logit`, `invlogit`, `ltmlogisst`, `rtmlogisst`, `eslogis`.
5. Conversion functions between parameters related to Kiener distributions K1, K2, K3, K4:
 - `aw2k`, `aw2d`, `aw2e`, `ad2e`, `ad2k`, `ad2w`, `ae2d`, `ae2k`, `ae2w`, `ak2e`, `ak2w`, `de2a`, `de2k`, `de2w`, `dk2a`, `dk2e`, `dw2a`, `dw2e`, `dw2k`, `ek2a`, `ak2d`, `ek2w`, `aw2a`, `aw2d`, `ew2a`, `aw2d`, `ew2k`, `kd2a`, `kd2e`, `kd2w`, `ke2a`, `ke2d`, `ke2w`, `kw2a`, `kw2d`, `kw2e`.
 - `pk2pk`.
6. Kiener distributions K1, K2, K3, K4 and the new K7 (introduced in v1.7-0):
 - `d`, `p`, `q`, `r`, `dp`, `dq`, `l`, `dl`, `ql`, `var`, `ltm`, `rtm`, `dtmq`, es `kiener1`,
 - `d`, `p`, `q`, `r`, `dp`, `dq`, `l`, `dl`, `ql`, `var`, `ltm`, `rtm`, `dtmq`, es `kiener2`,
 - `d`, `p`, `q`, `r`, `dp`, `dq`, `l`, `dl`, `ql`, `var`, `ltm`, `rtm`, `dtmq`, es `kiener3`,
 - `d`, `p`, `q`, `r`, `dp`, `dq`, `l`, `dl`, `ql`, `var`, `ltm`, `rtm`, `dtmq`, es `kiener4`,
 - `d`, `p`, `q`, `r`, `dp`, `dq`, `l`, `dl`, `ql`, `var`, `ltm`, `rtm`, `dtmq`, es `kiener7`.
7. Quantile (VaR) corrective function (as a multiplier of the logistic function). Expected shortfall corrective function (as a multiplier of the expected shortfall of the logistic distribution):
 - `ckiener1`, `ckiener2`, `ckiener3`, `ckiener4`, `ckiener7`.
 - `hkiener1`, `hkiener2`, `hkiener3`, `hkiener4`, `hkiener7`.
8. Moments of the distribution estimated from the dataset and from the regression parameters:

- [xmoments](#).
 - [kmoments](#), [kmoment](#), [kcmoment](#), [kmean](#), [kstandev](#), [kvariance](#), [kskewness](#), [kkurtosis](#), [kecurtosis](#).
9. Regression and estimation functions to estimate Kiener distribution parameters on a given dataset. `*fit*` and `*param*` are wrappers of algorithms `reg` and `estim`. `reg` uses an unweighted nonlinear regression function. `estim` uses a fast estimation based on quantiles:
- [regkienerLX](#), [laplacegaussnorm](#).
 - [fitkienerX](#).
 - [paramkienerX](#), [paramkienerX5](#), [paramkienerX7](#).
10. Functions related to `paramkienerX`:
- [elevenprobs](#), [sevenprobs](#), [fiveprobs](#).
 - [estimkiener11](#), [estimkiener7](#), [estimkiener5](#).
 - [roundcoefk](#).
 - [checkcoefk](#).
11. Predefined subsets of parameters to extract them from the long vector `fitk` obtained after regression/estimation `regkienerLX`, `fitkienerX` :
- [exfit0](#), ..., [exfit7](#).

For a quick start, jump to the functions [regkienerLX](#), [fitkienerX](#) and run the examples. Then, download and read the documents in pdf format cited in the references to get an overview on the major functions. Finally, explore the other examples.

```

Description

Conversion functions between parameters a, k, w, d, e used in Kiener distributions K2, K3 and K4.

Usage

aw2k(a, w)

aw2d(a, w)

aw2e(a, w)

ad2e(a, d)

ad2k(a, d)

ad2w(a, d)

ae2d(a, e)

ae2k(a, e)

ae2w(a, e)

ak2d(a, k)

ak2e(a, k)

ak2w(a, k)

de2a(d, e)

de2k(d, e)

de2w(d, e)

dk2a(d, k)

dk2e(d, k)

dk2w(d, k)

dw2a(d, w)

dw2e(d, w)

dw2k(d, w)

ek2a(e, k)

ek2d(e, k)

ek2w(e, k)

ew2a(e, w)

ew2d(e, w)

ew2k(e, w)

kd2a(k, d)

kd2e(k, d)

kd2w(k, d)

ke2a(k, e)

ke2d(k, e)

ke2w(k, e)

kw2a(k, w)

kw2d(k, w)

kw2e(k, w)

Arguments

a	a numeric value.
w	a numeric value.
d	a numeric value.
e	a numeric value.
k	a numeric value.

Details

a (alpha) is the left tail parameter, w (omega) is the right tail parameter, d (delta) is the distortion parameter, e (epsilon) is the eccentricity parameter. k (kappa) is the harmonic mean of a and w and describes a global tail parameter. They are defined by:

- $aw2k(a, w) = k = \frac{2}{\frac{1}{a} + \frac{1}{w}}$
- $aw2d(a, w) = d = \frac{-\frac{1}{a} + \frac{1}{w}}{2}$
- $aw2e(a, w) = e = \frac{a-w}{a+w}$
- $kd2a(k, d) = a = \frac{1}{\frac{1}{k} - d}$

- $kd2w(k, d) = w = \frac{1}{\frac{1}{k} + d}$
- $ke2a(k, e) = a = \frac{k}{1 - e}$
- $ke2w(k, e) = w = \frac{k}{1 + e}$
- $ke2d(k, e) = d = \frac{e}{k}$
- $kd2e(k, d) = e = k * d$
- $de2k(k, e) = k = \frac{e}{d}$

checkcoefk

Check Coefk

Description

Check that coefk is either a vector of length 7 or a matrix with 7 columns or an array with length of last dimension equal to 7.

Usage

```
checkcoefk(coefk, dim = c(1, 2), STOP = TRUE)
```

Arguments

coefk	numeric, matrix or data.frame representing parameters $c(m, g, a, k, w, d, e)$.
dim	numeric. Accepted dimension(s) for coefk: 1 for vector, 2 for matrix, 3 for array. List is not accepted. Default is $c(1, 2)$.
STOP	boolean. If an error is encountered, TRUE stops the function and returns an error message. FALSE just returns FALSE.

Examples

```
(coefk <- paramkienerX(getDSdata()))
checkcoefk(coefk)
checkcoefk(t(coefk), STOP = FALSE)
```

checkquantiles	<i>Check Quantiles and Probabilities</i>
----------------	--

Description

Check that quantiles (or probabilities) are all different from each other and correctly ordered. If `proba = TRUE`, check that values are in range (0, 1).

Usage

```
checkquantiles(x, proba = FALSE, acceptNA = FALSE, STOP = TRUE)
```

Arguments

<code>x</code>	vector of quantiles.
<code>proba</code>	boolean. If <code>TRUE</code> , check range (0,1).
<code>acceptNA</code>	boolean. If <code>FALSE</code> , NA value are not accepted.
<code>STOP</code>	boolean. If an error is encountered, <code>TRUE</code> stops the function and returns an error message. <code>FALSE</code> just returns <code>FALSE</code> .

Examples

```
lst <- list(
  0.8,
  c(0.1, 0.5, 0.8),
  c(0.1, 0.5, 0.8, 0.2),
  c(2, 3, 1),
  c(2, 3),
  -0.01,
  NA,
  c(NA, NA),
  c(0.1, NA),
  c(0.1, NA, 0.5, 0.8),
  c(0.1, NA, 0.8, NA, 0.5),
  c(12, NA)
)

## Evaluate
for (i in seq_along(lst)) {
  cat(i, lst[[i]], " : ",
      checkquantiles(lst[[i]], proba = FALSE, STOP = FALSE),
      checkquantiles(lst[[i]], proba = TRUE, STOP = FALSE),
      checkquantiles(lst[[i]], proba = FALSE, acceptNA = TRUE, STOP = FALSE),
      checkquantiles(lst[[i]], proba = TRUE, acceptNA = TRUE, STOP = FALSE),
      "\n")
}
```

```
sapply(1st, checkquantiles, proba = TRUE, acceptNA = TRUE, STOP = FALSE)

## Not run:
checkquantiles(matrix((1:12)/16, ncol=3), proba = TRUE, STOP = FALSE)
## End(Not run)
```

ckiener1234

Quantile (VaR) and Expected Shortfall Corrective Functions

Description

Quantile functions (or VaR) and Expected Shortfall of Kiener distributions K1, K2, K3 and K4, usually calculated at $pprobs2 = c(0.01, 0.025, 0.05, 0.95, 0.975, 0.99)$, can be expressed as:

1. Quantile of the logit function multiplied by a fat tail (c)orrective function ckiener1234;
2. Expected s(h)ortfall of the logistic function multiplied by a corrective function hkiener1234.

Both functions ckiener1234 and hkiener1234 are independant from the scale parameter g and are indirect measures of the tail curvature. A value close to 1 indicates a model similar to the logistic function with almost no curvature and probably parameter $k > 8$. When k (or a, w) decreases, the values of c and h increase and indicate some more pronounced symmetric or asymmetric curvature, depending on values of d, e. Note that if $(\min(a, k, w) \leq 1)$, ckiener1234 still exists but the expected shortfall and hkiener1234 become undefined (NA).

Some financial applications use threshold values on ckiener1234 or hkiener1234 to select or discard stocks over time as they become less or more risky.

Usage

```
hkiener1(p, m = 0, g = 1, k = 3.2, lower.tail = TRUE, log.p = FALSE)
```

```
hkiener2(p, m = 0, g = 1, a = 3.2, w = 3.2, lower.tail = TRUE,
log.p = FALSE)
```

```
hkiener3(p, m = 0, g = 1, k = 3.2, d = 0, lower.tail = TRUE,
log.p = FALSE)
```

```
hkiener4(p, m = 0, g = 1, k = 3.2, e = 0, lower.tail = TRUE,
log.p = FALSE)
```

```
hkiener7(p, coefk = c(0, 1, 3.2, 3.2, 3.2, 0, 0), lower.tail = TRUE,
log.p = FALSE)
```

```
ckiener1(p, k = 3.2, lower.tail = TRUE, log.p = FALSE)
```

```
ckiener2(p, a = 3.2, w = 3.2, lower.tail = TRUE, log.p = FALSE)
```

```

ckiener3(p, k = 3.2, d = 0, lower.tail = TRUE, log.p = FALSE)
ckiener4(p, k = 3.2, e = 0, lower.tail = TRUE, log.p = FALSE)
ckiener7(p, coefk = c(0, 1, 3.2, 3.2, 3.2, 0, 0), lower.tail = TRUE,
log.p = FALSE)

```

Arguments

p	numeric or vector of probabilities.
m	numeric. parameter m used in model K1, K2, K3 and K4.
g	numeric. parameter g used in model K1, K2, K3 and K4.
k	numeric. parameter k used in model K1, K3 and K4.
lower.tail	logical. If TRUE, use p. If FALSE, use 1-p.
log.p	logical. If TRUE, probabilities p are given as log(p).
a	numeric. parameter a used in model K2.
w	numeric. parameter w used in model K2.
d	numeric. parameter d used in model K3.
e	numeric. parameter e used in model K4.
coefk	vector or 7 columns-matrix representing parameters c(m,g,a,k,w,d,e) obtained from paramkienerX .

See Also

dfData

Datasets dfData, mData, tData, xData, zData, extractData : dfData

Description

A list of datasets in data.frame, matrix, timeSeries, xts and zoo formats. This is the data.frame format. Visit [extractData](#) for more information.

elevate	<i>Elevate</i>
---------	----------------

Description

A transformation to turn negative prices into positive prices and maintain at the same time the hierarchy between all prices.

Usage

```
elevate(X, e = NULL)
```

Arguments

X	The prices.
e	numeric. The focal point of the hyperbola.

Details

Negative prices in financial markets, like interest rates in Europe, are a nightmare as the rough calculation of the returns generates non-sense values. `elevate` uses an hyperbola and implements the following formula:

$$\text{elevate}(x, e) = \frac{x + \sqrt{x^2 + e^2}}{2}$$

There is currently no rule of thumb to calculate `e`. When `e = NULL`, there is no change and the output is identical to the input. When `e = 0`, all negative values are turned to 0.

Examples

```
require(graphics)

X <- (-50:100)/5
plot( X, elevate(X, e = 5), type = "l", ylim = c(0, 20) )
lines(X, elevate(X, e = 2), col = 2)
lines(X, elevate(X, e = 1), col = 3)
lines(X, elevate(X, e = 0.5), col = 4)
lines(X, elevate(X, e = 0), col = 1)
```

elevenprobs

Eleven, Seven, Five Probabilities

Description

Extract from a dataset X a vector of 11, 7 or 5 probabilities:

- $c(p_1, p_2, p_3, 0.25, 0.35, 0.50, 0.65, 0.75, 1-p_3, 1-p_2, 1-p_1)$
- $c(p_1, p_2, 0.25, 0.50, 0.75, 1-p_2, 1-p_1)$
- $c(p_1, 0.25, 0.50, 0.75, 1-p_1)$

where p_1 , p_2 and p_3 are the most extreme probabilities with values finishing by $..01$, $..025$ or $..05$ that can be extracted from the dataset X . Parameters names are displayed if `parnames = TRUE`.

From version 1.8-0, p_1 and $1-p_1$ can be associated to the i -th and $(N-i)$ -th element.

Usage

```
elevenprobs(X, parnames = FALSE)
```

```
sevenprobs(X, parnames = FALSE)
```

```
fiveprobs(X, i = 4, parnames = FALSE)
```

Arguments

<code>X</code>	numeric. Vector of quantiles.
<code>parnames</code>	boolean. Output parameter vector with or without names.
<code>i</code>	integer. The i -th and $(N-i)$ -th elements for which the probabilities p_1 and $1-p_1$ are calculated. If $(i == 0)$, the method used before version 1.8-0 : the extreme finishing by $..01$, $..025$ or $..05$.

mtext(eX, side = 4, at = leX, las = 1, line = -3.3)

```

 estimkiener11

Estimation Functions with 5, 7 or 11 Quantiles

Description

Several functions to estimate the parameters of asymmetric Kiener distributions with just 5, 7 or 11 quantiles.

Usage

```
estimkiener11(x11, p11, ord = 7, maxk = 10)
```

```
estimkiener7(x7, p7, maxk = 10)
```

```
estimkiener5(x5, p5, maxk = 20, maxe = 0.9)
```

Arguments

ord	integer. Option for probability selection and treatment.
maxk	numeric. Maximum value for k (kappa).
x5, x7, x11	vector of 5, 7 or 11 quantiles.
p5, p7, p11	vector of 5, 7 or 11 probabilities.
maxe	numeric. Maximum value for abs(e) (epsilon). Maximum is maxe = 1.

Details

These functions, called by paramkienerX5, paramkienerX7, [paramkienerX](#), use 5, 7 or 11 probabilities and quantiles to estimate the parameters of Kiener distributions.

p5, x5 are obtained with functions fiveprobs(X) and quantile(p5).

p7, x7 are obtained with functions sevenprobs(X) and quantile(p7).

p11, x11 are obtained with functions elevenprobs(X) and quantile(p11).

The extraction of the 11 probabilities is controlled with the option ord which can take 12 integer values, ord = 7 being the default. Small dataset should consider ord = 5 and large dataset can consider ord = 12:

1. `c(p1, 0.35, 0.50, 0.65, 1-p1)`
2. `c(p2, 0.35, 0.50, 0.65, 1-p2)`
3. `c(p1, p2, 0.35, 0.50, 0.65, 1-p2, 1-p1)`
4. `c(p1, p2, p3, 0.35, 0.50, 0.65, 1-p3, 1-p2, 1-p1)`
5. `c(p1, 0.25, 0.50, 0.75, 1-p1)`
6. `c(p2, 0.25, 0.50, 0.75, 1-p2)`
7. `c(p1, p2, 0.25, 0.50, 0.75, 1-p2, 1-p1)`
8. `c(p1, p2, p3, 0.25, 0.50, 0.75, 1-p3, 1-p2, 1-p1)`
9. `c(p1, 0.25, 0.35, 0.50, 0.65, 0.75, 1-p1)`
10. `c(p2, 0.25, 0.35, 0.50, 0.65, 0.75, 1-p2)`
11. `c(p1, p2, 0.25, 0.35, 0.50, 0.65, 0.75, 1-p2, 1-p1)`
12. `c(p1, p2, p3, 0.25, 0.35, 0.50, 0.65, 0.75, 1-p3, 1-p2, 1-p1)`

`p5 = fiveprobs(X)` corresponds to `c(p1, 0.25, 0.50, 0.75, 1-p1)`.

`p7 = sevenprobs(X)` corresponds to `c(p1, p2, 0.25, 0.50, 0.75, 1-p2, 1-p1)`.

The above probabilities are then transferred to the `quantile` function whose parameter `type` can change significantly the extracted quantiles. Our experience is that `type = 6` is appropriate when $k > 1.9$ and `type = 5` is appropriate when $k < 1.9$. Other types `type = 8` and `type = 9` can be considered as well. The other types should be ignored. (Note: when $k < 1.5$, algorithm `algo = "reg"` returns better results).

Parameter `maxk` controls the maximum allowed value for estimated parameter `k`. Reasonable values are `maxk = 10, 15, 20`. Default is `maxk = 10` to be consistent with `regkienerLX`.

extractData	<i>Datasets dfData, mData, tData, xData, zData, extractData : extract-Data</i>
-------------	--

Description

dfData, mData, tData, xData, zData are datasets made of lists of data.frame, matrix, timeSeries, xts and zoo components. They describe prices and returns of 10 financial series used in the documents and demos presented at 8th and 9th R/Rmetrics conferences (2014, 2015). See the references. The last serie (CHF, interest rates in Switzerland) exhibits negative prices. All distributions of logreturns exhibit fat tails. Function extractData converts subsets of mData, tData, xData, zData.

Usage

```
extractData(pr = "p", ft = "tss", start = "2007-01-01",
            end = "2013-12-31")
```

Arguments

pr	character. Extract prices or returns: c("p", "r", "prices", "returns").
ft	character. Output format among c("tss", "xts", "zoo", "dfr", "bfr", "mat").
start	character. Start date.
end	character. End date.

Examples

```

library(zoo)
library(xts)
library(timeSeries)

### dfData, tData, xData, zData : prices only
attributes(dfData); attributes(tData); attributes(xData); attributes(zData)
lapply(dfData, head, 3)
lapply( mData, head, 3)
lapply( tData, head, 3)
lapply( xData, head, 3)
lapply( zData, head, 3)

### extractData : prices and logreturns
head(ptD <- extractData("p", "tss", "2009-01-01", "2012-12-31")) ; tail(ptD)
head(rtD <- extractData("r", "tss"))
head(pxD <- extractData("p", "xts"))
head(rxD <- extractData("r", "xts"))
head(pzD <- extractData("p", "zoo"))
head(rzD <- extractData("r", "zoo"))
head(pbD <- extractData("p", "bfr"))
head(rbD <- extractData("r", "bfr"))
head(pmD <- extractData("p", "mat"))
head(rmD <- extractData("r", "mat"))

### Remove item CHF (negative prices) from dfData, tData, xData, zData
Z <- dfData[names(dfData)[1:9]]; attributes(Z)
Z <- tData[names(tData)[1:9]]; attributes(Z)
Z <- xData[names(xData)[1:9]]; attributes(Z)
Z <- zData[names(zData)[1:9]]; attributes(Z)

```

fatreturns

Simple and Elaborated Prices to Returns

Description

fatreturns is an elaborated function to compute prices to returns. It includes a pre-treatment for negative prices. It computes either log-returns (default) or percentage-returns. It handles properly NA values in the input vector, replacing them by 0 in the output vector. Doing so, it warrants that the sum of the log-returns (when selected) is equal to the difference of the log-prices. It works with vector, matrix, data.frame, timeSeries, xts, zoo, list, list of lists and even list of vector, data.frame, timeSeries, xts, zoo mixed together. The returned object is of same dimension and same class than the input object with the first line filled with 0. The results may be as per one, per cent (default), per thousand and per ten thousand.

logreturns is an improved version of function $100 * \text{diff}(\log(x))$ to handle vector, matrix, data.frame and list. It handles properly the first line and the NA values. It does not control time, rownames and colnames but may return them.

Usage

```
fatreturns(x, log = TRUE, per = "cent", e = NULL, dfrcol = 1,
  na.rm = TRUE)
```

```
logreturns(x)
```

```
replaceNA(x)
```

Arguments

x	The prices (vector, data.frame, matrix, timeSeries, xts, zoo, list).
log	boolean. log returns or percentage returns.
per	character. Either "one", "cent", "thousand", "tenthousand" or "o", "c", "th", "te". Multiply the result by 1, 100, 1000, 10000.
e	NULL or positive numeric. NULL is for no change $f(x)=x$. A positive numeric designates the focal point of the hyperbola to turn negative prices into positive prices, keeping the hierarchy: $f(x)=(x+\sqrt{x*x+e*e})/2$. There is currently no rules of thumb for the optimal value of e. See elevate .
dfrcol	integer. For data.frame only, designates the column that handles the time and must be processed separately. Use <code>dfrcol = 0</code> if all columns must be processed and there is no time (or turn the data.frame to a matrix).
na.rm	boolean. Replace $x[t]=NA$ with the previous non-NA value available in the price serie such that $(x[t-1], x[t]=x[t-1], x[t+1])$ and calculate the returns accordingly. Force 0 in the first line of the returns if $x[1]=NA$.

Examples

```
fatreturns(extractData())
logreturns(extractData())
```

Description

Several functions to estimate the parameters of asymmetric Kiener distributions and display the results in a numeric vector or in a matrix. Algorithm "reg" (the default) uses a nonlinear regression and handle difficult cases. Algorithm "estim" has been completely rewritten in version 1.8-0 and is now very accurate, even for $k < 1$. Adjustment on extreme quantiles can be controlled very precisely.

Usage

```
fitkienerX(X, algo = c("r", "reg", "e", "estim"), ord = 7, maxk = 10,
  mink = 1.53, maxe = 0.5, probak = pprobs2, dgts = NULL,
  exfitk = NULL, dimnames = FALSE, ncores = 1)
```

```
paramkienerX(X, algo = c("r", "reg", "e", "estim"), ord = 7, maxk = 10,
  mink = 1.53, maxe = 0.5, dgts = 3, parnames = TRUE,
  dimnames = FALSE, ncores = 1)
```

```
paramkienerX7(X, dgts = 3, n = 10, maxk = 20, maxe = 0.9,
  parnames = TRUE, dimnames = FALSE, ncores = 1)
```

```
paramkienerX5(X, dgts = 3, i = 4, maxk = 20, maxe = 0.9,
  parnames = TRUE, dimnames = FALSE, ncores = 1)
```

Arguments

X	numeric. Vector, matrix, array or list of quantiles.
algo	character. The algorithm used: "r" or "reg" for regression (default) and "e" or "estim" for quantile estimation.
ord	integer. Option for probability selection and treatment.
maxk	numeric. The maximum value of tail parameter k.
mink	numeric. The minimum value of tail parameter k.
maxe	numeric. The maximum value of absolute tail parameter e .
probak	numeric. Ordered vector of probabilities.
dgts	integer. The rounding of output parameters.
exfitk	character. A vector of parameter names to subset the output.
dimnames	boolean. Display dimnames.
ncores	integer. The number of cores for parallel processing of arrays.
parnames	boolean. Display parameter names.
n	integer. The 1:n and (N+i-n):N elements of X used to calculate synthetic quantiles at probability levels p1 and 1-p1.
i	integer. The i-th and (N-i)-th elements of X used to extract probabilities p1 and 1-p1 and quantiles x(p) and x(1-p).

Details

FatTailsR package currently uses two different algorithms to estimate the parameters of Kiener distributions K1, K2, K3 and K4.

- Functions `fitkienerX(algo = "reg")`, `paramkienerX(algo = "reg")` and `regkienerLX` use an unweighted nonlinear regression from $\text{logit}(p)$ to X over the whole dataset. Depending the size of the dataset, calculation can be slow but is usually accurate and describes very well the last 1-10 points in the tails (except if there is a huge outlier).

- Functions `fitkienerX(algo = "estim")`, `paramkienerX(algo = "estim")`, `paramkienerX5` and `paramkienerX7` estimate the parameters with just 5 to 11 quantiles, 5 being the minimum. For averaging purpose, 11 quantiles are proposed (see below). Computation is almost instantaneous and reasonably accurate. This is the recommended method for intensive computation.

A typical input is a numeric vector or a matrix that describes the returns of a stock. A matrix must be in the format DS with DATES as rownames, STOCKS as colnames and (log-)returns as the content of the matrix. An array must be in the format DSL with DATES as rownames, STOCKS as colnames LAGS in the third dimension and (log-)returns as the content of the array. A list can be a list of numeric but neither a list of matrix, a list of data.frame or a list of arrays.

Conversion from a (possible) time series format to a sorted numeric vector is done automatically and without any check of the initial format. Empirical probabilities of each point in the sorted dataset is calculated with the function `ppoints` whose parameter `a` has been set to `a = 0` as large datasets are very common in finance. The lowest acceptable size of a dataset is not clear at this moment. A minimum of 11 points has been set in "reg" algorithm and a minimum of 15 points has been set in "estim" algorithm. It might change in the future. If possible, use at least 21 points.

Parameter `algo` controls the algorithm used. Default is "reg".

When `algo = "reg"` (or `algo = "r"`), a nonlinear regression is performed with `nlsLM` from the logit of the empirical probabilities $\logit(p)$ over the quantiles X with the function `qlkiener4`. The maximum value of the tail parameter k is controlled by `maxk`. An upper value `maxk = 10` is appropriate for datasets of low and medium size, less than 20.000 or 50.000 points. For larger datasets, the upper limit can be extended up to `maxk = 20`. When this limit is reached, the shape of the distribution is very similar to the logistic distribution (at least when $e = 0$) and the use of this distribution should be considered. Remember that value $k < 2$ describes a distribution with no stable variance and $k < 1$ describes a distribution with no stable mean.

When `algo = "estim"` (or `algo = "e"`), 5 to 11 quantiles are used to estimate the parameters. The minimum is 5 quantiles : the median $x.50$, two quantiles at medium distance to the median, usually $x.25$ and $x.75$ and two quantiles located close to the extremes of the dataset, for instance $x.01$ and $x.99$ if the dataset X has more than 100 points, $x.0001$ and $x.9999$ if the dataset X has more than 10.000 points and so on if the dataset is larger. These quantiles are extracted with function `fiveprobs`. Small datasets must contain at least 15 different points.

With the idea of averaging the results (but without any guarantee of better estimates), calculation has been extended to 11 probabilities extracted from X with the function `elevenprobs` where $p1$, $p2$ and $p3$ are the most extreme probabilities of the dataset X with values finishing either by `.x01` or `.x025` or `.x05`:

- $p11 = c(p1, p2, p3, 0.25, 0.35, 0.50, 0.65, 0.75, 1-p3, 1-p2, 1-p1)$

Selection of subsets among these 11 probabilities is controlled with the option `ord` which can take 12 different values. For instance, the default `ord = 7` computes the parameters at probabilities $c(p1, 0.25, 0.50, 0.75, 1-p1)$ and $c(p2, 0.25, 0.50, 0.75, 1-p2)$. Parameters d and k are averaged first and the results of these averages are used to compute the other parameters g , a , w , e . Small dataset should consider `ord = 5` and large dataset can consider `ord = 12`. The 12 possible values of `ord` are:

1. $c(p1, 0.35, 0.50, 0.65, 1-p1)$
2. $c(p2, 0.35, 0.50, 0.65, 1-p2)$
3. $c(p1, p2, 0.35, 0.50, 0.65, 1-p2, 1-p1)$

4. $c(p1, p2, p3, 0.35, 0.50, 0.65, 1-p3, 1-p2, 1-p1)$
5. $c(p1, 0.25, 0.50, 0.75, 1-p1)$
6. $c(p2, 0.25, 0.50, 0.75, 1-p2)$
7. $c(p1, p2, 0.25, 0.50, 0.75, 1-p2, 1-p1)$
8. $c(p1, p2, p3, 0.25, 0.50, 0.75, 1-p3, 1-p2, 1-p1)$
9. $c(p1, 0.25, 0.35, 0.50, 0.65, 0.75, 1-p1)$
10. $c(p2, 0.25, 0.35, 0.50, 0.65, 0.75, 1-p2)$
11. $c(p1, p2, 0.25, 0.35, 0.50, 0.65, 0.75, 1-p2, 1-p1)$
12. $c(p1, p2, p3, 0.25, 0.35, 0.50, 0.65, 0.75, 1-p3, 1-p2, 1-p1)$

paramkienerX5 is a simplified version of paramkienerX with predefined values algo = "estim", ord = 5, maxk = 10 and direct access to internal subfunctions. It uses the following probabilities:

- $p5 = c(p1, 0.25, 0.50, 0.75, 1-p1)$

paramkienerX7 is a simplified version of paramkienerX with predefined values algo = "estim", ord = 7, maxk = 10 and direct access to internal subfunctions. It uses the following probabilities:

- $p7 = c(p1, p2, 0.25, 0.50, 0.75, 1-p2, 1-p1)$

The quantiles corresponding to the above probabilities are then extracted with the function [quantile](#) whose parameter type has been set to type = 6 as it returns the closest values to the true quantiles (according to our experience) for all $k > 1.9$. (Note: when $k < 1.5$, algorithm algo = "reg" returns better results). Both probabilities and quantiles are then transferred to [estimkiener11](#) for calculation.

probak controls the probabilities at which the model is tested with the parameter estimates. fitkienerX and [regkienerLX](#) share the same subroutines. The default for fitkienerX and regkienerLX is $pprobs2 = c(0.01, 0.025, 0.05, 0.95, 0.975, 0.99)$ as those values are usual in finance. Other sets of values are provided at [pprobs0](#).

Rounding the results is useful to display nice results, especially in a matrix or in a data.frame. dgts = 13 is recommended as a, k, w are usually significant at 1 digit.

- dgts = NULL does not perform any rounding.
- dgts = 0 to 9 rounds all parameters at the same level.
- dgts = 10 to 27 rounds the parameters at various levels for nice display. See [roundcoefk](#) for the details. (Note: the rounding 10 to 27 currently works with paramkienerX, paramkienerX5, paramkienerX7 but not yet with fitkienerX).

Extracting the most useful parameters from the (quite long) vector/matrix fitk is controlled by parameter exfitk that calls user-defined or predefined parameter subsets like [exfit0](#), ..., [exfit7](#). IMPORTANT: never subset fitk by rank number as new items may be added in the future and rank may vary.

Calculation of vectors, matrices and lists is not parallelized. Parallelization of code for arrays was introduced in version 1.5-0 and improved in version 1.5-1. ncores controls the number of cores allowed to the process (through [parApply](#) which runs on Unices and Windows and requires about 2 seconds to start). ncores = 1 means no parallelization. ncores = 0 is the recommended option. It uses the maximum number of cores available on the computer, as detected by [detectCores](#),

minus 1 core, which gives the best performance in most cases. Although appealing, this automatic selection may be sometimes dangerous. For instance, the instruction $f(X, ncores_max) - f(X, ncores_max)$, a nice way to compute an array of 0, will call 2 $ncores_max$ and crash R. $ncores = 2, \dots, 99$ sets manually the number of cores. If the requested value is larger than the maximum number of cores, this value is automatically reduced (with a warning) to this maximum. Hence, this latest option provides one core more than option $ncores = 0$.

NOTE: `fitkienerLX`, `regkienerX`, `estimkiener(X, 5, 7)` were introduced in v1.2-0 and replaced in version v1.4-1 by `fitkienerX` and `paramkiener(X, 5, 7)` to accommodate vector, matrix, arrays and lists. We apologize to early users who need to rewrite their codes.

Value

`paramkienerX`: a vector (or a matrix) of parameter estimates $c(m, g, a, k, w, d, e)$.

`fitkienerX`: a vector (or a matrix) made of several parts:

- `ret` : the return over the period calculated with `sum(x)`. Thus, assume log-returns.
- `m, g, a, k, w, d, e` : the parameter estimates.
- `m1, sd, sk, ke` : the mean, standard deviation, skewness and excess of kurtosis computed from the parameter estimates.
- `m1x, sdx, skx, kex` : The mean, standard deviation, skewness and excess of kurtosis computed from the dataset.
- `lh` : the length of the dataset over the period.
- `q.` : quantile estimated with the parameter estimates.
- `VaR.` : Value-at-Risk, positive in most cases.
- `c.` : corrective tail coefficient = $(q - m) / (q_logistic_function - m)$.
- `ltm.` : left tail mean (signed ES on the left tail, usually negative).
- `rtm.` : right tail mean (signed ES on the right tail, usually positive).
- `dtmq.` : ($p \leq 0.5$ left, $p > 0.5$ right) tail mean minus quantile.
- `ES.` : expected shortfall, positive in most cases.
- `h.` : corrective ES = $(ES - m) / (ES_logistic_function - m)$.
- `desv.` : $ES - VaR$, usually positive.
- `l.` : quantile estimated by the tangent logistic function.
- `d1.` : quantile - `quantile_logistic_function`.
- `g.` : quantile estimated by the Laplace-Gauss function.
- `dg.` : quantile - `quantile_Laplace_Gauss_function`.

IMPORTANT : if you need to subset `fitk`, always subset it by parameter names and never subset it by rank number as new items may be added in the future and rank may vary. Use for instance `exfit0, ..., exfit7`.

## paramkienerX7(arr, ncores = 2) - paramkienerX(arr, ncores = 2)
## End(Not run)

### End

```

`getDSdata`*Get DS Dataset*

Description

A function to extract the log-returns of 16 financial series and time series provided by the packages `datasets` (`EuStockMarkets`, `sunspot.year`) and `timeSeries` (`USDCHF`, `MSFT`, `LPP2005REC`). The 16 datasets are converted to a list of numeric without any reference to the original dates. This list is usually called `DS`, hence the name.

Usage

```
getDSdata()
```

Details

The dataset is usually created by the instruction `DS <- getDSdata()`. Then, it is used with a call to `DS[[j]]` with `j` in `1:16`.

1. "USDCHF" (`USDCHF`, `timeSeries`)
2. "MSFT" (`MSFT`, `timeSeries`)
3. "DAX" (`EuStockMarkets`, `datasets`)
4. "SMI" (`EuStockMarkets`, `datasets`)
5. "CAC" (`EuStockMarkets`, `datasets`)
6. "FTSE" (`EuStockMarkets`, `datasets`)
7. "SBI" (`LPP2005REC`, `timeSeries`)
8. "SPI" (`LPP2005REC`, `timeSeries`)
9. "SII" (`LPP2005REC`, `timeSeries`)
10. "LMI" (`LPP2005REC`, `timeSeries`)
11. "MPI" (`LPP2005REC`, `timeSeries`)
12. "ALT" (`LPP2005REC`, `timeSeries`)
13. "LPP25" (`LPP2005REC`, `timeSeries`)
14. "LPP40" (`LPP2005REC`, `timeSeries`)
15. "LPP60" (`LPP2005REC`, `timeSeries`)
16. "sunspot" (`sunspot.year`, `datasets`)

Note that `sunspot.year` is regularly updated with each new version of R. The generated dataset is `logreturn(sunspot.year + 1000)`.

Examples

```
require(timeSeries)

getDSdata
DS <- getDSdata()
attributes(DS)
sapply(DS, length)
sapply(DS, head)
```

getnamesk

Generate a list of vectors of characters from a vector of probabilities

Description

Generate vector of characters from a vector of probabilities, replacing 0. by letters:

- p. : probability.
- q. : quantile.
- VaR. : Value-at-Risk, positive in most cases.
- c. : corrective tail coefficient = $(q - m) / (q_logistic_function - m)$.
- ltm. : left tail mean (signed ES on the left tail, usually negative).
- rtm. : right tail mean (signed ES on the right tail, usually positive).
- dtmq. : ($p \leq 0.5$ left, $p > 0.5$ right) tail mean minus quantile.
- ES. : expected shortfall, positive in most cases.
- h. : corrective ES = $(ES - m) / (ES_logistic_function - m)$.
- desv. : ES - VaR, usually positive.
- l. : quantile of the tangent logistic function.
- dl. : quantile - quantile_logistic_function.
- g. : quantile of the Laplace-Gauss function.
- dg. : quantile - quantile_Laplace_Gauss_function.

, q., VaR., c., ltm., rtm., ES., h., l., dl., g., dg.. The result is a list of vectors.

Usage

```
getnamesk(probak = pprobs2, check = TRUE)
```

```
getnprobak(probak = pprobs2, check = TRUE)
```

Arguments

probak a vector of ordered probabilities with 0 and 1 excluded.
check boolean. Apply [checkquantiles](#) function.

Examples

```
getnamesk(pprobs1)
getnamesk(pprobs8)
```

kashp	<i>Kashp Function</i>
-------	-----------------------

Description

kashp, which stands for kappa times arc-sine-hyperbola-power is the nonlinear transformation of x at the heart of power hyperbolas, power hyperbolic functions and symmetric Kiener distributions. dkashp_dx is its derivative with respect to x. ashp is provided for convenience.

Usage

```
kashp(x, k = 1)
```

```
dkashp_dx(x, k = 1)
```

```
ashp(x, k = 1)
```

Arguments

x a numeric value, vector or matrix.
k a numeric value or vector, preferably strictly positive.

Details

ashp function is defined for x in (-Inf, +Inf) by:

$$ashp(x, k) = asinh(x/k)$$

kashp function is defined for x in (-Inf, +Inf) by:

$$kashp(x, k) = k * asinh(x/k)$$

dkashp_dx function is defined for x in (-Inf, +Inf) by:

$$\frac{d}{dx} kashp(x, k) = \frac{1}{\sqrt{(x/k)^2 + 1}} = \frac{1}{\cosh(ashp(x, k))}$$

If k is a vector, then the use of the function [outer](#) is recommended.

The undesired case k=0 returns 0 for kashp and dkashp_dx.

Examples

```

require(graphics)

### FUNCTIONS kashp, dkashp_dx, ashp
xx <- (-3:3)*3
x <- (-9:9) ; names(x) <- x
k <- c(9999, 8, 5, 3, 2, 1) ; names(k) <- k

```

kiener1

Symmetric Kiener Distribution K1

Description

Density, distribution function, quantile function, random generation, value-at-risk, expected short-fall (+ signed left/right tail mean) and additional formulae for symmetric Kiener distribution K1. This distribution is similar to the power hyperbola logistic distribution but with additional parameters for location (m) and scale (g).

Usage

```

dkiener1(x, m = 0, g = 1, k = 3.2, log = FALSE)

pkiener1(q, m = 0, g = 1, k = 3.2, lower.tail = TRUE, log.p = FALSE)

qkiener1(p, m = 0, g = 1, k = 3.2, lower.tail = TRUE, log.p = FALSE)

rkiener1(n, m = 0, g = 1, k = 3.2)

```

```

dpkiener1(p, m = 0, g = 1, k = 3.2, log = FALSE)
dqkiener1(p, m = 0, g = 1, k = 3.2, log = FALSE)
lkiener1(x, m = 0, g = 1, k = 3.2)
dlkiener1(lp, m = 0, g = 1, k = 3.2, log = FALSE)
qlkiener1(lp, m = 0, g = 1, k = 3.2, lower.tail = TRUE)
varkiener1(p, m = 0, g = 1, k = 3.2, lower.tail = TRUE,
  log.p = FALSE)
ltmkiener1(p, m = 0, g = 1, k = 3.2, lower.tail = TRUE,
  log.p = FALSE)
rtmkiener1(p, m = 0, g = 1, k = 3.2, lower.tail = TRUE,
  log.p = FALSE)
dtmqkiener1(p, m = 0, g = 1, k = 3.2, lower.tail = TRUE,
  log.p = FALSE)
eskiener1(p, m = 0, g = 1, k = 3.2, lower.tail = TRUE, log.p = FALSE,
  signedES = FALSE)

```

Arguments

x	vector of quantiles.
m	numeric. The median.
g	numeric. The scale parameter, preferably strictly positive.
k	numeric. The tail parameter, preferably strictly positive.
log	logical. If TRUE, densities are given in log scale.
q	vector of quantiles.
lower.tail	logical. If TRUE, use p. If FALSE, use 1-p.
log.p	logical. If TRUE, probabilities p are given as log(p).
p	vector of probabilities.
n	number of observations. If length(n) > 1, the length is taken to be the number required.
lp	vector of logit of probabilities.
signedES	logical. FALSE (default) returns positive numbers for left and right tails. TRUE returns negative number (= ltmkiener1) for left tail and positive number (= rtmkiener1) for right tail.

Details

Kiener distributions use the following parameters, some of them being redundant. See [aw2k](#) and [pk2pk](#) for the formulas and the conversion between parameters:

- m (μ) is the median of the distribution,.
- g (γ) is the scale parameter.
- a (α) is the left tail parameter.
- k (κ) is the harmonic mean of a and w and describes a global tail parameter.
- w (ω) is the right tail parameter.
- d (δ) is the distortion parameter.
- e (ϵ) is the eccentricity parameter.

Kiener distributions $K1(m, g, k, \dots)$ describe distributions with symmetric left and right fat tails and with a tail parameter k . This parameter is the power exponent mentioned in the Pareto formula and Karamata theorems.

m is the median of the distribution. g is the scale parameter and is linked for any value of k to the density at the median through the relation

$$g * f(x = m, g = g) = \frac{\pi}{4\sqrt{3}} \approx 0.453$$

When $k = \text{Inf}$, g is very close to $\text{sd}(x)$. NOTE: In order to match this standard deviation, the value of g has been updated from versions $< 1.9.0$ by a factor $\frac{2\pi}{\sqrt{3}}$.

The functions `dkiener1`, `pkienner1` and `lkiener1` have an explicit form (whereas `dkiener2347`, `pkienner2347` and `lkiener2347` have no explicit forms).

`dkiener1` function is defined for x in $(-\text{Inf}, +\text{Inf})$ by:

$$y = \frac{1}{k} \frac{\pi}{\sqrt{3}} \frac{(x-m)}{g}$$

$$dkienner1(x, m, g, k) = \pi * \left[2\sqrt{3} g \sqrt{y^2 + 1} (1 + \cosh(k * asinh(y))) \right]^{-1}$$

`pkienner1` function is defined for q in $(-\text{Inf}, +\text{Inf})$ by:

$$y = \frac{1}{k} \frac{\pi}{\sqrt{3}} \frac{(x-m)}{g}$$

$$pkienner1(q, m, g, k) = 1 / (1 + \exp(-k * asinh(y)))$$

`qkiener1` function is defined for p in $(0, 1)$ by:

$$qkiener1(p, m, g, k) = m + \frac{\sqrt{3}}{\pi} * g * k * \sinh\left(\frac{\text{logit}(p)}{k}\right)$$

`rkiener1` generates n random quantiles.

In addition to the classical `d`, `p`, `q`, `r` functions, the prefixes `dp`, `dq`, `l`, `dl`, `ql` are also provided.

`dpkiener1` is the density function calculated from the probability p . It is defined for p in $(0, 1)$ by:

$$dpkiener1(p, m, g, k) = \frac{\pi}{\sqrt{3}} \frac{p(1-p)}{g} \text{sech}\left(\frac{\text{logit}(p)}{k}\right)$$

dqkiener1 is the derivate of the quantile function calculated from the probability p. It is defined for p in (0, 1) by:

$$dqkiener1(p, m, g, k) = \frac{\sqrt{3}}{\pi} \frac{g}{p(1-p)} \cosh\left(\frac{\text{logit}(p)}{k}\right)$$

lkiener1 function is equivalent to kashp function but with additional parameters m and g. Being computed from the x (or q) vector, it can be compared to the logit of the empirical probability logit(p) through a nonlinear regression with ordinary or weighted least squares to estimate the distribution parameters. It is defined for x in (-Inf, +Inf) by:

$$y = \frac{1}{k} \frac{\pi}{\sqrt{3}} \frac{(x-m)}{g}$$

$$lkiener1(q, m, g, k) = k * \text{asinh}(y)$$

dlkiener1 is the density function calculated from the logit of the probability lp = logit(p). It is defined for lp in (-Inf, +Inf) by:

$$dlkiener1(lp, m, g, k) = \frac{\pi}{\sqrt{3}} \frac{p(1-p)}{g} \text{sech}\left(\frac{lp}{k}\right)$$

qlkiener1 is the quantile function calculated from the logit of the probability lp = logit(p). It is defined for lp in (-Inf, +Inf) by:

$$qlkiener1(p, m, g, k) = m + \frac{\sqrt{3}}{\pi} * g * k * 2 * \sinh\left(\frac{lp}{k}\right)$$

varkiener1 designates the Value a-risk and turns negative numbers into positive numbers with the following rule:

$$varkiener1 < -if (p <= 0.5) (-qkiener1) \text{ else } (qkiener1)$$

Usual values in finance are p = 0.01, p = 0.05, p = 0.95 and p = 0.99. lower.tail = FALSE uses 1-p rather than p.

ltmkiener1, rtmkiener1 and eskkiener1 are respectively the left tail mean, the right tail mean and the expected shortfall of the distribution (sometimes called average VaR, conditional VaR or tail VaR). Left tail mean is the integrale from -Inf to p of the quantile function qkiener1 divided by p. Right tail mean is the integrale from p to +Inf of the quantile function qkiener1 divided by 1-p. Expected shortfall turns negative numbers into positive numbers with the following rule:

$$eskkiener1 < -if (p <= 0.5) (-ltmkiener1) \text{ else } (rtmkiener1)$$

Usual values in finance are p = 0.01, p = 0.025, p = 0.975 and p = 0.99. lower.tail = FALSE uses 1-p rather than p.

dtmqkiener1 is the difference between the left tail mean and the quantile when (p <= 0.5) and the difference between the right tail mean and the quantile when (p > 0.5). It is in quantile unit and is an indirect measure of the tail curvature.

  log.p = FALSE, signedES = FALSE)

```

Arguments

x	vector of quantiles.
m	numeric. The median.
g	numeric. The scale parameter, preferably strictly positive.
a	numeric. The left tail parameter, preferably strictly positive.
w	numeric. The right tail parameter, preferably strictly positive.
log	logical. If TRUE, densities are given in log scale.
q	vector of quantiles.
lower.tail	logical. If TRUE, use p. If FALSE, use 1-p.

log.p	logical. If TRUE, probabilities p are given as log(p).
p	vector of probabilities.
n	number of observations. If length(n) > 1, the length is taken to be the number required.
lp	vector of logit of probabilities.
signedES	logical. FALSE (default) returns positive numbers for left and right tails. TRUE returns negative number (= ltmkiener4) for left tail and positive number (= rtmkiener4) for right tail.

Details

Kiener distributions use the following parameters, some of them being redundant. See [aw2k](#) and [pk2pk](#) for the formulas and the conversion between parameters:

- m (mu) is the median of the distribution,.
- g (gamma) is the scale parameter.
- a (alpha) is the left tail parameter.
- k (kappa) is the harmonic mean of a and w and describes a global tail parameter.
- w (omega) is the right tail parameter.
- d (delta) is the distortion parameter.
- e (epsilon) is the eccentricity parameter.

Kiener distributions $K2(m, g, a, w)$ are distributions with asymmetrical left and right fat tails described by the parameters a (alpha) for the left tail and w (omega) for the right tail. These parameters correspond to the power exponent that appear in Pareto formula and Karamata theorems.

As a and w are highly correlated, the use of Kiener distributions ($K3(\dots, k, d)$ $K4(K4(\dots, k, e)$) is an alternate solution.

m is the median of the distribution. g is the scale parameter and is linked for any value of a and w to the density at the median through the relation

$$g * f(x = m, g = g) = \frac{\pi}{4\sqrt{3}} \approx 0.453$$

When a = Inf and w = Inf, g is very close to sd(x). NOTE: In order to match this standard deviation, the value of g has been updated from versions < 1.9.0 by a factor $\frac{2\pi}{\sqrt{3}}$.

The functions `dkiener2347`, `pkkiener2347` and `lkiener2347` have no explicit forms. Due to a poor optimization algorithm, their calculations in versions < 1.9 were unreliable. In versions > 1.9, a much better algorithm was found and the optimization is conducted in a fast way to avoid a lengthy optimization. The two extreme elements (minimum, maximum) of the given x or q arguments are sent to a second order optimizer that minimize the residual error of the `lkiener2347` function and return the estimated lower and upper logit values. Then a sequence of logit values of length 51 times the length of x or q is generated between these lower and upper values and the corresponding quantiles are calculated with the function `qlkiener2347`. These 51 times more numerous quantiles are then compared to the original x or q arguments and the closest values with their associated logit values are selected. The probabilities are then calculated with the function `invlogit` and the densities are calculated with the function `dlkiener2347`. The accuracy of this approach depends

on the sparsity of the initial x or q sequences. A 4 digits accuracy can be expected, enough for most usages.

qkiener2 function is defined for p in (0, 1) by:

$$qkiener2(p, m, g, a, w) = m + \frac{\sqrt{3}}{\pi} * g * k * \left(-exp\left(-\frac{logit(p)}{a} + \frac{logit(p)}{w}\right) \right)$$

where k is the harmonic mean of the tail parameters a and w calculated by $k = aw2k(a, w)$. rkiener2 generates n random quantiles.

In addition to the classical d, p, q, r functions, the prefixes dp, dq, l, dl, ql are also provided.

dpkiener2 is the density function calculated from the probability p. It is defined for p in (0, 1) by:

$$dpkiener2(p, m, g, a, w) = \frac{\pi}{\sqrt{3}} \frac{p(1-p)}{g} \frac{2}{k} \left[+\frac{1}{a} exp\left(-\frac{logit(p)}{a}\right) + \frac{1}{w} exp\left(\frac{logit(p)}{w}\right) \right]^{-1}$$

dqkiener2 is the derivate of the quantile function calculated from the probability p. It is defined for p in (0, 1) by:

$$dqkiener2(p, m, g, a, w) = \frac{\sqrt{3}}{\pi} \frac{g}{p(1-p)} \frac{k}{2} \left[+\frac{1}{a} exp\left(-\frac{logit(p)}{a}\right) + \frac{1}{w} exp\left(\frac{logit(p)}{w}\right) \right]$$

dlkiener2 is the density function calculated from the logit of the probability lp = logit(p) defined in (-Inf, +Inf) by:

$$dlkiener2(lp, m, g, a, w) = \frac{\pi}{\sqrt{3}} \frac{p(1-p)}{g} \frac{2}{k} \left[+\frac{1}{a} exp\left(-\frac{lp}{a}\right) + \frac{1}{w} exp\left(\frac{lp}{w}\right) \right]^{-1}$$

qlkiener2 is the quantile function calculated from the logit of the probability. It is defined for lp in (-Inf, +Inf) by:

$$qlkiener2(lp, m, g, a, w) = m + \frac{\sqrt{3}}{\pi} * g * k * \left(-exp\left(-\frac{lp}{a} + \frac{lp}{w}\right) \right)$$

varkiener2 designates the Value a-risk and turns negative numbers into positive numbers with the following rule:

$$varkiener2 < -if (p <= 0.5) (-qkiener2) else (qkiener2)$$

Usual values in finance are p = 0.01, p = 0.05, p = 0.95 and p = 0.99. lower.tail = FALSE uses 1-p rather than p.

ltmkiener2, rtmkiener2 and eskiener2 are respectively the left tail mean, the right tail mean and the expected shortfall of the distribution (sometimes called average VaR, conditional VaR or tail VaR). Left tail mean is the integrale from -Inf to p of the quantile function qkiener2 divided by p. Right tail mean is the integrale from p to +Inf of the quantile function qkiener2 divided by 1-p. Expected shortfall turns negative numbers into positive numbers with the following rule:

$$eskiener2 < -if (p <= 0.5) (-ltmkiener2) else (rtmkiener2)$$

Usual values in finance are p = 0.01, p = 0.025, p = 0.975 and p = 0.99. lower.tail = FALSE uses 1-p rather than p.

dtmqkiener2 is the difference between the left tail mean and the quantile when (p <= 0.5) and the difference between the right tail mean and the quantile when (p > 0.5). It is in quantile unit and is an indirect measure of the tail curvature.

`kiener3`*Asymmetric Kiener Distribution K3*

Description

Density, distribution function, quantile function, random generation, value-at-risk, expected short-fall (+ signed left/right tail mean) and additional formulae for asymmetric Kiener distribution K3.

Usage

```
dkien3(x, m = 0, g = 1, k = 3.2, d = 0, log = FALSE)
```

```
pkien3(q, m = 0, g = 1, k = 3.2, d = 0, lower.tail = TRUE,  
log.p = FALSE)
```

```
qkien3(p, m = 0, g = 1, k = 3.2, d = 0, lower.tail = TRUE,  
log.p = FALSE)
```

```
rkiener3(n, m = 0, g = 1, k = 3.2, d = 0)
```

```
dpkiener3(p, m = 0, g = 1, k = 3.2, d = 0, log = FALSE)
```

```
dqkiener3(p, m = 0, g = 1, k = 3.2, d = 0, log = FALSE)
```

```
lkiener3(x, m = 0, g = 1, k = 3.2, d = 0)
```

```
dlkiener3(lp, m = 0, g = 1, k = 3.2, d = 0, log = FALSE)
```

```
qlkiener3(lp, m = 0, g = 1, k = 3.2, d = 0, lower.tail = TRUE)
```

```
varkiener3(p, m = 0, g = 1, k = 3.2, d = 0, lower.tail = TRUE,  
log.p = FALSE)
```

```
lrmkiener3(p, m = 0, g = 1, k = 3.2, d = 0, lower.tail = TRUE,  
log.p = FALSE)
```

```
rtmkiener3(p, m = 0, g = 1, k = 3.2, d = 0, lower.tail = TRUE,  
log.p = FALSE)
```

```
dtmqkiener3(p, m = 0, g = 1, k = 3.2, d = 0, lower.tail = TRUE,  
log.p = FALSE)
```

```
eskiener3(p, m = 0, g = 1, k = 3.2, d = 0, lower.tail = TRUE,  
log.p = FALSE, signedES = FALSE)
```

Arguments

`x` vector of quantiles.

m	numeric. The median.
g	numeric. The scale parameter, preferably strictly positive.
k	numeric. The tail parameter, preferably strictly positive.
d	numeric. The distortion parameter between left and right tails.
log	logical. If TRUE, densities are given in log scale.
q	vector of quantiles.
lower.tail	logical. If TRUE, use p. If FALSE, use 1-p.
log.p	logical. If TRUE, probabilities p are given as log(p).
p	vector of probabilities.
n	number of observations. If length(n) > 1, the length is taken to be the number required.
lp	vector of logit of probabilities.
signedES	logical. FALSE (default) returns positive numbers for left and right tails. TRUE returns negative number (= ltmkiener3) for left tail and positive number (= rtmkiener3) for right tail.

Details

Kiener distributions use the following parameters, some of them being redundant. See [aw2k](#) and [pk2pk](#) for the formulas and the conversion between parameters:

- m (mu) is the median of the distribution,.
- g (gamma) is the scale parameter.
- a (alpha) is the left tail parameter.
- k (kappa) is the harmonic mean of a and w and describes a global tail parameter.
- w (omega) is the right tail parameter.
- d (delta) is the distortion parameter.
- e (epsilon) is the eccentricity parameter.

Kiener distributions K3(m, g, k, d, . . .) are distributions with asymmetrical left and right fat tails described by a global tail parameter k and a distortion parameter d.

Distributions K3 ([kiener3](#)) with parameters k (kappa) and d (delta) and distributions K4 ([kiener4](#)) with parameters k (kappa) and e (epsilon) have been created to disentangle the parameters a (alpha) and w (omega) of distributions of distribution K2 ([kiener2](#)). The tiny difference between distributions K3 and K4 ($d = e/k$) has not yet been fully evaluated. Both should be tested at that moment.

k is the harmonic mean of a and w and represents a global tail parameter.

d is a distortion parameter between the left tail parameter a and the right tail parameter w. It verifies the inequality: $-k < d < k$ (whereas e of distribution K4 verifies $-1 < e < 1$). The conversion functions (see [aw2k](#)) are:

$$\frac{1}{k} = \frac{1}{2} \left(\frac{1}{a} + \frac{1}{w} \right)$$

$$d = \frac{1}{2} \left(-\frac{1}{a} + \frac{1}{w} \right)$$

$$\frac{1}{a} = \frac{1}{k} - d$$

$$\frac{1}{w} = \frac{1}{k} + d$$

d (and e) should be of the same sign than the skewness. A negative value $d < 0$ implies $a < w$ and indicates a left tail heavier than the right tail. A positive value $d > 0$ implies $a > w$ and a right tail heavier than the left tail.

m is the median of the distribution. g is the scale parameter and is linked for any value of k and d to the density at the median through the relation

$$g * dkiener3(x = m, g = g, d = d) = \frac{\pi}{4\sqrt{3}} \approx 0.453$$

When $k = \text{Inf}$, g is very close to $\text{sd}(x)$. NOTE: In order to match this standard deviation, the value of g has been updated from versions $< 1.9.0$ by a factor $\frac{2\pi}{\sqrt{3}}$.

The functions `dkiener2347`, `pkienner2347` and `lkienner2347` have no explicit forms. Due to a poor optimization algorithm, their calculations in versions < 1.9 were unreliable. In versions > 1.9 , a much better algorithm was found and the optimization is conducted in a fast way to avoid a lengthy optimization. The two extreme elements (minimum, maximum) of the given x or q arguments are sent to a second order optimizer that minimize the residual error of the `lkienner2347` function and return the estimated lower and upper logit values. Then a sequence of logit values of length 51 times the length of x or q is generated between these lower and upper values and the corresponding quantiles are calculated with the function `qlkiener2347`. These 51 times more numerous quantiles are then compared to the original x or q arguments and the closest values with their associated logit values are selected. The probabilities are then calculated with the function `invlogit` and the densities are calculated with the function `dlkiener2347`. The accuracy of this approach depends on the sparsity of the initial x or q sequences. A 4 digits accuracy can be expected, enough for most usages.

`qkiener3` function is defined for p in $(0, 1)$ by:

$$qkiener3(p, m, g, k, d) = m + \frac{\sqrt{3}}{\pi} * g * k * \sinh\left(\frac{\text{logit}(p)}{k}\right) * \exp(d * \text{logit}(p))$$

`rkiener3` generates n random quantiles.

In addition to the classical d, p, q, r functions, the prefixes `dp, dq, l, dl, ql` are also provided.

`dpkiener3` is the density function calculated from the probability p . The formula is adapted from distribution K2. It is defined for p in $(0, 1)$ by:

$$dpkiener3(p, m, g, k, d) = \frac{\pi}{\sqrt{3}} \frac{p(1-p)}{g} \frac{2}{k} \left[+\frac{1}{a} \exp\left(-\frac{\text{logit}(p)}{a}\right) + \frac{1}{w} \exp\left(\frac{\text{logit}(p)}{w}\right) \right]^{-1}$$

with a and w defined from k and d with the formula presented above.

`dqkiener3` is the derivate of the quantile function calculated from the probability p . The formula is adapted from distribution K2. It is defined for p in $(0, 1)$ by:

$$dqkiener3(p, m, g, k, d) = \frac{\sqrt{3}}{\pi} \frac{g}{p(1-p)} \frac{k}{2} \left[+\frac{1}{a} \exp\left(-\frac{\text{logit}(p)}{a}\right) + \frac{1}{w} \exp\left(\frac{\text{logit}(p)}{w}\right) \right]$$

with a and w defined above.

$dlkiener3$ is the density function calculated from the logit of the probability $lp = \text{logit}(p)$ defined in $(-\text{Inf}, +\text{Inf})$. The formula is adapted from distribution K2:

$$dlkiener2(lp, m, g, k, e) = \frac{\pi}{\sqrt{3}} \frac{p(1-p)}{g} \frac{2}{k} \left[+\frac{1}{a} \exp\left(-\frac{lp}{a}\right) + \frac{1}{w} \exp\left(\frac{lp}{w}\right) \right]^{-1}$$

with a and w defined above.

$qlkiener3$ is the quantile function calculated from the logit of the probability. It is defined for lp in $(-\text{Inf}, +\text{Inf})$ by:

$$qlkiener3(lp, m, g, k, d) = m + \frac{\sqrt{3}}{\pi} * g * k * \sinh\left(\frac{lp}{k}\right) * \exp(d * lp)$$

$varkiener3$ designates the Value at-risk and turns negative numbers into positive numbers with the following rule:

$$varkiener3 < -if (p \leq 0.5) (-qkiener3) \text{ else } (qkiener3)$$

Usual values in finance are $p = 0.01$, $p = 0.05$, $p = 0.95$ and $p = 0.99$. `lower.tail = FALSE` uses $1-p$ rather than p .

$ltmkiener3$, $rtmkiener3$ and $eskiener3$ are respectively the left tail mean, the right tail mean and the expected shortfall of the distribution (sometimes called average VaR, conditional VaR or tail VaR). Left tail mean is the integrale from $-\text{Inf}$ to p of the quantile function $qkiener3$ divided by p . Right tail mean is the integrale from p to $+\text{Inf}$ of the quantile function $qkiener3$ divided by $1-p$. Expected shortfall turns negative numbers into positive numbers with the following rule:

$$eskiener3 < -if (p \leq 0.5) (-ltmkiener3) \text{ else } (rtmkiener3)$$

Usual values in finance are $p = 0.01$, $p = 0.025$, $p = 0.975$ and $p = 0.99$. `lower.tail = FALSE` uses $1-p$ rather than p .

$dtmqkiener3$ is the difference between the left tail mean and the quantile when $(p \leq 0.5)$ and the difference between the right tail mean and the quantile when $(p > 0.5)$. It is in quantile unit and is an indirect measure of the tail curvature.

Asymmetric Kiener Distribution K4

Description

Density, distribution function, quantile function, random generation, value-at-risk, expected short-fall (+ signed left/right tail mean) and additional formulae for asymmetric Kiener distribution K4.

Usage

```
dkiener4(x, m = 0, g = 1, k = 3.2, e = 0, log = FALSE)
```

```
pkiener4(q, m = 0, g = 1, k = 3.2, e = 0, lower.tail = TRUE,
  log.p = FALSE)
```

```

qkiener4(p, m = 0, g = 1, k = 3.2, e = 0, lower.tail = TRUE,
  log.p = FALSE)

rkiener4(n, m = 0, g = 1, k = 3.2, e = 0)

dpkiener4(p, m = 0, g = 1, k = 3.2, e = 0, log = FALSE)

dqkiener4(p, m = 0, g = 1, k = 3.2, e = 0, log = FALSE)

lkiener4(x, m = 0, g = 1, k = 3.2, e = 0)

dlkiener4(lp, m = 0, g = 1, k = 3.2, e = 0, log = FALSE)

qlkiener4(lp, m = 0, g = 1, k = 3.2, e = 0, lower.tail = TRUE)

varkiener4(p, m = 0, g = 1, k = 3.2, e = 0, lower.tail = TRUE,
  log.p = FALSE)

ltmkiener4(p, m = 0, g = 1, k = 3.2, e = 0, lower.tail = TRUE,
  log.p = FALSE)

rtmkiener4(p, m = 0, g = 1, k = 3.2, e = 0, lower.tail = TRUE,
  log.p = FALSE)

dtmqkiener4(p, m = 0, g = 1, k = 3.2, e = 0, lower.tail = TRUE,
  log.p = FALSE)

eskiener4(p, m = 0, g = 1, k = 3.2, e = 0, lower.tail = TRUE,
  log.p = FALSE, signedES = FALSE)

```

Arguments

x	vector of quantiles.
m	numeric. The median.
g	numeric. The scale parameter, preferably strictly positive.
k	numeric. The tail parameter, preferably strictly positive.
e	numeric. The eccentricity parameter between left and right tails.
log	logical. If TRUE, densities are given in log scale.
q	vector of quantiles.
lower.tail	logical. If TRUE, use p. If FALSE, use 1-p.
log.p	logical. If TRUE, probabilities p are given as log(p).
p	vector of probabilities.
n	number of observations. If length(n) > 1, the length is taken to be the number required.
lp	vector of logit of probabilities.

signedES logical. FALSE (default) returns positive numbers for left and right tails. TRUE returns negative number (= ltmkiener4) for left tail and positive number (= rtmkiener4) for right tail.

Details

Kiener distributions use the following parameters, some of them being redundant. See [aw2k](#) and [pk2pk](#) for the formulas and the conversion between parameters:

- m (mu) is the median of the distribution,.
- g (gamma) is the scale parameter.
- a (alpha) is the left tail parameter.
- k (kappa) is the harmonic mean of a and w and describes a global tail parameter.
- w (omega) is the right tail parameter.
- d (delta) is the distortion parameter.
- e (epsilon) is the eccentricity parameter.

Kiener distributions K4(m, g, k, e, . . .) are distributions with asymmetrical left and right fat tails described by a global tail parameter k and an eccentricity parameter e.

Distributions K3 ([kiener3](#)) with parameters k (kappa) and d (delta) and distributions K4 ([kiener4](#)) with parameters k (kappa) and e (epsilon) have been created to disentangle the parameters a (alpha) and w (omega) of distributions K2 ([kiener2](#)). The tiny difference between distributions K3 and K4 ($d = e/k$) has not yet been fully evaluated. Both should be tested at that moment.

k is the harmonic mean of a and w and represents a global tail parameter.

e is an eccentricity parameter between the left tail parameter a and the right tail parameter w. It verifies the inequality: $-1 < e < 1$ (whereas d of distribution K3 verifies $-k < d < k$). The conversion functions (see [aw2k](#)) are:

$$1/k = (1/a + 1/w)/2$$

$$e = (a - w)/(a + w)$$

$$a = k/(1 - e)$$

$$w = k/(1 + e)$$

e (and d) should be of the same sign than the skewness. A negative value $e < 0$ implies $a < w$ and indicates a left tail heavier than the right tail. A positive value $e > 0$ implies $a > w$ and a right tail heavier than the left tail.

m is the median of the distribution. g is the scale parameter and is linked for any value of k and e to the density at the median through the relation

$$g * dkiener4(x = m, g = g, e = e) = \frac{\pi}{4\sqrt{3}} \approx 0.453$$

When $k = \text{Inf}$, g is very close to $\text{sd}(x)$. NOTE: In order to match this standard deviation, the value of g has been updated from versions < 1.9.0 by a factor $\frac{2\pi}{\sqrt{3}}$.

The functions `dkiener2347`, `pkiener2347` and `lkiener2347` have no explicit forms. Due to a poor optimization algorithm, their calculations in versions < 1.9 were unreliable. In versions > 1.9, a much better algorithm was found and the optimization is conducted in a fast way to avoid a lengthy optimization. The two extreme elements (minimum, maximum) of the given `x` or `q` arguments are sent to a second order optimizer that minimize the residual error of the `lkiener2347` function and return the estimated lower and upper logit values. Then a sequence of logit values of length 51 times the length of `x` or `q` is generated between these lower and upper values and the corresponding quantiles are calculated with the function `qlkiener2347`. These 51 times more numerous quantiles are then compared to the original `x` or `q` arguments and the closest values with their associated logit values are selected. The probabilities are then calculated with the function `invlogit` and the densities are calculated with the function `dlkiener2347`. The accuracy of this approach depends on the sparsity of the initial `x` or `q` sequences. A 4 digits accuracy can be expected, enough for most usages.

`qkiener4` function is defined for `p` in (0, 1) by:

$$qkiener4(p, m, g, k, e) = m + \frac{\sqrt{3}}{\pi} * g * k * \sinh\left(\frac{\text{logit}(p)}{k}\right) * \exp\left(\frac{e}{k} \text{logit}(p)\right)$$

`rkiener4` generates `n` random quantiles.

In addition to the classical `d`, `p`, `q`, `r` functions, the prefixes `dp`, `dq`, `l`, `dl`, `ql` are also provided.

`dpkiener4` is the density function calculated from the probability `p`. The formula is adapted from distribution K2. It is defined for `p` in (0, 1) by:

$$dpkiener4(p, m, g, k, e) = \frac{\pi}{\sqrt{3}} \frac{p(1-p)}{g} \frac{2}{k} \left[+\frac{1}{a} \exp\left(-\frac{\text{logit}(p)}{a}\right) + \frac{1}{w} \exp\left(\frac{\text{logit}(p)}{w}\right) \right]^{-1}$$

with `a` and `w` defined from `k` and `e`.

`dqkiener4` is the derivate of the quantile function calculated from the probability `p`. The formula is adapted from distribution K2. It is defined for `p` in (0, 1) by:

$$dqkiener4(p, m, g, k, e) = \frac{\sqrt{3}}{\pi} \frac{g}{p(1-p)} \frac{k}{2} \left[+\frac{1}{a} \exp\left(-\frac{\text{logit}(p)}{a}\right) + \frac{1}{w} \exp\left(\frac{\text{logit}(p)}{w}\right) \right]$$

with `a` and `w` defined with the formula presented above.

`dlkiener4` is the density function calculated from the logit of the probability `lp = logit(p)` defined in (-Inf, +Inf). The formula is adapted from distribution K2:

$$dlkiener2(lp, m, g, k, e) = \frac{\pi}{\sqrt{3}} \frac{p(1-p)}{g} \frac{2}{k} \left[+\frac{1}{a} \exp\left(-\frac{lp}{a}\right) + \frac{1}{w} \exp\left(\frac{lp}{w}\right) \right]^{-1}$$

with `a` and `w` defined above.

`qlkiener4` is the quantile function calculated from the logit of the probability. It is defined for `lp` in (-Inf, +Inf) by:

$$qlkiener4(lp, m, g, k, e) = m + \frac{\sqrt{3}}{\pi} * g * k * \sinh\left(\frac{lp}{k}\right) * \exp\left(\frac{e}{k} lp\right)$$

`varkiener4` designates the Value a-risk and turns negative numbers into positive numbers with the following rule:

$$varkiener4 < -if (p <= 0.5) (-qkiener4) else (qkiener4)$$

Usual values in finance are $p = 0.01$, $p = 0.05$, $p = 0.95$ and $p = 0.99$. `lower.tail = FALSE` uses $1-p$ rather than p .

`ltmkiener4`, `rtmkiener4` and `eskiener4` are respectively the left tail mean, the right tail mean and the expected shortfall of the distribution (sometimes called average VaR, conditional VaR or tail VaR). Left tail mean is the integrale from $-\text{Inf}$ to p of the quantile function `qkiener4` divided by p . Right tail mean is the integrale from p to $+\text{Inf}$ of the quantile function `qkiener4` divided by $1-p$. Expected shortfall turns negative numbers into positive numbers with the following rule:

$$eskiener4 < -if (p <= 0.5) (-ltmkiener4) \text{ else } (rtmkiener4)$$

Usual values in finance are $p = 0.01$, $p = 0.025$, $p = 0.975$ and $p = 0.99$. `lower.tail = FALSE` uses $1-p$ rather than p .

`dtmqkiener4` is the difference between the left tail mean and the quantile when ($p \leq 0.5$) and the difference between the right tail mean and the quantile when ($p > 0.5$). It is in quantile unit and is an indirect measure of the tail curvature.

### END EXAMPLE 4

```

Description

Density, distribution function, quantile function, random generation, value-at-risk, expected short-fall (+ signed left/right tail mean) and additional formulae for asymmetric Kiener distribution K7 =

K2. With K7, the vector of parameters is provided as `coefk`, usually estimated with `paramkienerX` (and `~X5,~X7`) or `regkienerLX$coefk`. Main inputs can be supplied as vector (`x, q, p`) and matrix (`coefk`) and the resulting output is a matrix (useful for simulation).

Usage

```

dkiener7(x, coefk = c(0, 1, 3.2, 3.2, 3.2, 0, 0), log = FALSE)

pkiener7(q, coefk = c(0, 1, 3.2, 3.2, 3.2, 0, 0), lower.tail = TRUE,
  log.p = FALSE)

qkiener7(p, coefk = c(0, 1, 3.2, 3.2, 3.2, 0, 0), lower.tail = TRUE,
  log.p = FALSE)

rkiener7(n, coefk = c(0, 1, 3.2, 3.2, 3.2, 0, 0), same_p = FALSE)

dpkiener7(p, coefk = c(0, 1, 3.2, 3.2, 3.2, 0, 0), log = FALSE)

dqkiener7(p, coefk = c(0, 1, 3.2, 3.2, 3.2, 0, 0), log = FALSE)

lkiener7(x, coefk = c(0, 1, 3.2, 3.2, 3.2, 0, 0))

dlkiener7(lp, coefk = c(0, 1, 3.2, 3.2, 3.2, 0, 0), log = FALSE)

qlkiener7(lp, coefk = c(0, 1, 3.2, 3.2, 3.2, 0, 0), lower.tail = TRUE)

varkiener7(p, coefk = c(0, 1, 3.2, 3.2, 3.2, 0, 0), lower.tail = TRUE,
  log.p = FALSE)

ltmkiener7(p, coefk = c(0, 1, 3.2, 3.2, 3.2, 0, 0), lower.tail = TRUE,
  log.p = FALSE)

rtmkiener7(p, coefk = c(0, 1, 3.2, 3.2, 3.2, 0, 0), lower.tail = TRUE,
  log.p = FALSE)

dtmqkiener7(p, coefk = c(0, 1, 3.2, 3.2, 3.2, 0, 0), lower.tail = TRUE,
  log.p = FALSE)

eskiener7(p, coefk = c(0, 1, 3.2, 3.2, 3.2, 0, 0), lower.tail = TRUE,
  log.p = FALSE, signedES = FALSE)

```

Arguments

<code>x</code>	vector of quantiles.
<code>coefk</code>	vector of 7 parameters <code>c(m, g, a, k, w, d, e)</code> or matrix with 7 columns.
<code>log</code>	logical. If TRUE, densities are given in log scale.
<code>q</code>	vector of quantiles.
<code>lower.tail</code>	logical. If TRUE, use <code>p</code> . If FALSE, use <code>1-p</code> .

log.p	logical. If TRUE, probabilities p are given as log(p).
p	vector of probabilities.
n	integer. Number of observations. If length(n) > 1, the length is taken to be the number required.
same_p	logical. If FALSE (default), random probabilities are generated on the fly. If TRUE, the same set of random probabilities is used for each line of coefk (if coefk is a matrix).
lp	vector of logit of probabilities.
signedES	logical. FALSE (default) returns positive numbers for left and right tails. TRUE returns negative number (= ltmkiener7) for left tail and positive number (= rtmkiener7) for right tail.

Details

Kiener distributions use the following parameters, some of them being redundant. See [aw2k](#) and [pk2pk](#) for the formulas and the conversion between parameters:

- m (mu) is the median of the distribution.
- g (gamma) is the scale parameter.
- a (alpha) is the left tail parameter.
- k (kappa) is the harmonic mean of a and w and describes a global tail parameter.
- w (omega) is the right tail parameter.
- d (delta) is the distortion parameter.
- e (epsilon) is the eccentricity parameter.

Kiener distribution K7 is designed after [kiener2](#) but uses as input coefk rather than m, g, a and w. m is the median of the distribution. g is the scale parameter and is linked for any value of a and w to the density at the median through the relation

$$g * dkiener7(x = m, coefk = coefk) = \frac{\pi}{4\sqrt{3}} \approx 0.453$$

When a = Inf and w = Inf, g is very close to sd(x). NOTE: In order to match this standard deviation, the value of g has been updated from versions < 1.9.0 by a factor $\frac{2\pi}{\sqrt{3}}$.

The functions dkiener2347, pkiener2347 and lkiener2347 have no explicit forms. Due to a poor optimization algorithm, their calculations in versions < 1.9 were unreliable. In versions > 1.9, a much better algorithm was found and the optimization is conducted in a fast way to avoid a lengthy optimization. The two extreme elements (minimum, maximum) of the given x or q arguments are sent to a second order optimizer that minimize the residual error of the lkiener2347 function and return the estimated lower and upper logit values. Then a sequence of logit values of length 51 times the length of x or q is generated between these lower and upper values and the corresponding quantiles are calculated with the function qlkiener2347. These 51 times more numerous quantiles are then compared to the original x or q arguments and the closest values with their associated logit values are selected. The probabilities are then calculated with the function invlogit and the densities are calculated with the function dlkiener2347. The accuracy of this approach depends

on the sparsity of the initial x or q sequences. A 4 digits accuracy can be expected, enough for most usages.

qkiener7 function is defined for p in (0, 1) by:

$$qkiener7(p, coefk) = m + \frac{\sqrt{3}}{\pi} * g * k * \left(-exp \left(-\frac{logit(p)}{a} + \frac{logit(p)}{w} \right) \right)$$

where k is the harmonic mean of the tail parameters a and w calculated by $k = aw2k(a, w)$.

rkiener7 generates n random quantiles.

In addition to the classical d, p, q, r functions, the prefixes dp, dq, l, dl, ql are also provided.

dpkiener7 is the density function calculated from the probability p. It is defined for p in (0, 1) by:

$$dpkiener7(p, coefk) = \frac{\pi}{\sqrt{3}} \frac{p(1-p)}{g} \frac{2}{k} \left[+\frac{1}{a} exp \left(-\frac{logit(p)}{a} \right) + \frac{1}{w} exp \left(\frac{logit(p)}{w} \right) \right]^{-1}$$

dqkiener7 is the derivate of the quantile function calculated from the probability p. It is defined for p in (0, 1) by:

$$dqkiener7(p, coefk) = \frac{\sqrt{3}}{\pi} \frac{g}{p(1-p)} \frac{k}{2} \left[+\frac{1}{a} exp \left(-\frac{logit(p)}{a} \right) + \frac{1}{w} exp \left(\frac{logit(p)}{w} \right) \right]$$

with a and w extracted from coefk.

dlkiener7 is the density function calculated from the logit of the probability lp = logit(p) defined in (-Inf, +Inf). The formula is adapted from distribution K2:

$$dlkiener7(lp, coefk) = \frac{\pi}{\sqrt{3}} \frac{p(1-p)}{g} \frac{2}{k} \left[+\frac{1}{a} exp \left(-\frac{lp}{a} \right) + \frac{1}{w} exp \left(\frac{lp}{w} \right) \right]^{-1}$$

qlkiener7 is the quantile function calculated from the logit of the probability. It is defined for lp in (-Inf, +Inf) by:

$$qlkiener7(lp, coefk) = m + \frac{\sqrt{3}}{\pi} * g * k * \left(-exp \left(-\frac{lp}{a} + \frac{lp}{w} \right) \right)$$

varkiener7 designates the Value at-risk and turns negative numbers into positive numbers with the following rule:

$$varkiener7 < -if (p <= 0.5) (-qkiener7) else (qkiener7)$$

Usual values in finance are p = 0.01, p = 0.05, p = 0.95 and p = 0.99. lower.tail = FALSE uses 1-p rather than p.

ltmkiener7, rtmkiener7 and eskiener7 are respectively the left tail mean, the right tail mean and the expected shortfall of the distribution (sometimes called average VaR, conditional VaR or tail VaR). Left tail mean is the integrale from -Inf to p of the quantile function qkiener7 divided by p. Right tail mean is the integrale from p to +Inf of the quantile function qkiener7 divided by 1-p. Expected shortfall turns negative numbers into positive numbers with the following rule:

$$eskiener7 < -if (p <= 0.5) (-ltmkiener7) else (rtmkiener7)$$

Usual values in finance are p = 0.01, p = 0.025, p = 0.975 and p = 0.99. lower.tail = FALSE uses 1-p rather than p.

dtmqkiener7 is the difference between the left tail mean and the quantile when (p <= 0.5) and the difference between the right tail mean and the quantile when (p > 0.5). It is in quantile unit and is an indirect measure of the tail curvature.

kmoments

Moments Associated To Kiener Distribution Parameters

Description

Non-central moments, central moments, mean, standard deviation, variance, skewness, kurtosis, excess of kurtosis and cumulants associated to the parameters of Kiener distributions K1, K2, K3 and K4. All-in-one vectors kmoments (estimated from the parameters) and xmoments (estimated from the vector of quantiles) are provided.

Usage

```

kmoments(coefk, model = "K2", lengthx = NA, dgts = NULL,
         dimnames = FALSE)

xmoments(x, dgts = NULL, dimnames = FALSE)

kmoment(n, coefk, model = "K2", dgts = NULL)

kcmoment(n, coefk, model = "K2", dgts = NULL)

kmean(coefk, model = "K2", dgts = NULL)

kstandev(coefk, model = "K2", dgts = NULL)

kvariance(coefk, model = "K2", dgts = NULL)

kskewness(coefk, model = "K2", dgts = NULL)

kkurtosis(coefk, model = "K2", dgts = NULL)

kekurtosis(coefk, model = "K2", dgts = NULL)

```

Arguments

coefk vector. Parameters of the distribution of length 3 ("K1"), length 4 (model = K2, K3, K4) and length 7 ("K7").

model	character. Model type, either "K2", "K3" or "K4" if coefk is of length 4. Type "K1" and "K7" may be provided but are ignored.
lengthx	integer. The length of the vector x used to calculate the parameters. See the details for matrix and lists.
dgts	integer. The rounding applied to the output.
dimnames	boolean. Display dimnames.
x	numeric. Vector of quantiles.
n	integer. The moment order.

Details

The non-central moments $m_1, m_2, m_3, m_4, \dots, m_n$, the central moments $u_1, u_2, u_3, u_4, \dots, u_n$ (where u stands for mu in Greek) and the cumulants $k_1, k_2, k_3, k_4, \dots, k_n$ (where k stands for kappa in Greek; not to be confounded with tail parameter "k" and models "K1", "K2", "K3", "K4") of order n exist only if $\min(a, k, w) > n$. The mean m_1 exists only if $\min(a, k, w) > 1$. The standard deviation sd and the variance u_2 exist only if $\min(a, k, w) > 2$. The skewness sk exists only if $\min(a, k, w) > 3$. The kurtosis ku and the excess of kurtosis ke exist only if $\min(a, k, w) > 4$.

coefk may take five different forms :

- $c(m, g, k)$ of length 3 for distribution "K1".
- $c(m, g, a, w)$ of length 4 for distribution "K2".
- $c(m, g, k, d)$ of length 4 for distribution "K3".
- $c(m, g, k, e)$ of length 4 for distribution "K4".
- $c(m, g, a, k, w, d, e)$ of length 7 (sometimes referred as "K7") provided by estimation/regression functions `paramkienerX`, `fitkienerX`, `regkienerLX` (via `"reg$coefk"`) and conversion function `pk2pk`.

Forms of length 3 and 7 are automatically recognized and do not require `model = "K1"` or `"K7"` which are ignored. Forms of length 4 require `model = "K2"`, `"K3"` or `"K4"`. Visit [pk2pk](#) for details on the parameter conversion function used within `kmoments`.

`xmoments` and `kmoments` provide all-in-one vectors.

`xmoments` is the traditional mean of squares, cubic and power 4 functions of non-central and central values of x, from which NA values have been removed. Therefore, length of x ignores NA values and may be different from the true length.

`kmoments` calls every specialized functions from order 1 to order 4 and uses the estimated parameters as inputs, not the initial dataset x. As it does not know *a priori* the length of x, this latest can be provided separately via `lengthx = length(x)`, `lengthx = nrow(x)` and `lengthx = sapply(x, length)` if x is a vector, a matrix or a list. See the examples.

Value

Vectors `kmoments` and `xmoments` have the following structure (with a third letter x added to `xmoments`):

ku	Kurtosis.
ke	Excess of kurtosis.

sk	Skewness.
sd	Standard deviation. Square root of the variance u2
m1	Mean.
m2	Non-central moment of second order.
m3	Non-central moment of third order.
m4	Non-central moment of fourth order.
u1	Central moment of first order. Should be 0.
u2	Central moment of second order. Variance
u3	Central moment of third order.
u4	Central moment of fourth order.
k1	Cumulant of first order. Should be 0.
k2	Cumulant of second order.
k3	Cumulant of third order.
k4	Cumulant of fourth order.
lh	Length of x, from which NA values were removed.
.....	.

```

laplacegaussnorm

Laplace-Gauss Normal Distribution Object

Description

An object designed after `regkienerLX` to summarize the information related to a given dataset when the Laplace-Gauss normal distribution is applied on it.

Usage

```
laplacegaussnorm(X)
```

Arguments

`X` vector of quantiles.

Details

This function is designed after `regkienerLX` to provide a similar framework.

Value

A list with the following data.frame:

- `dfrXPn`: data.frame. `X` = initial quantiles. `Pn` = estimated normal probabilities.
- `dfrXLn`: data.frame. `X` = initial quantiles. `Ln` = logit of estimated normal probabilities.
- `dfrXDn`: data.frame. `X` = initial quantiles. `Dn` = estimated normal density.
- `coefn`: numeric. The mean and the standard deviation of the dataset.
- `dfrQnPn`: data.frame. `Qn` = estimated quantiles of interest. `Pn` = probability.
- `dfrQnLn`: data.frame. `Qn` = estimated quantiles of interest. `Pn` = logit of probability.

See Also

The regression function [regkienerLX](#).

Examples

head(lgn$dfrXLn)
head(lgn$dfrXDn)
lgn$coefn
lgn$dfrQnPn
lgn$dfrQnLn

```

logisst

The Standardized Logistic Distribution

Description

Density, distribution function, quantile function, random generation, value-at-risk, left-tail mean, right-tail mean, expected shortfall for the standardized logistic distribution, equivalent to `dpqrlogis(..., scale = g*sqrt(3)/pi)`.

Usage

```

dlogisst(x, m = 0, g = 1, log = FALSE)

plogisst(q, m = 0, g = 1, lower.tail = TRUE, log.p = FALSE)

qlogisst(p, m = 0, g = 1, lower.tail = TRUE, log.p = FALSE)

rlogisst(n, m = 0, g = 1)

dplogisst(p, m = 0, g = 1, log = FALSE)

dqlogisst(p, m = 0, g = 1, k = 3.2, log = FALSE)

llogisst(x, m = 0, g = 1)

dllogisst(lp, m = 0, g = 1, k = 3.2, log = FALSE)

qllogisst(lp, m = 0, g = 1, k = 3.2, lower.tail = TRUE)

varlogisst(p, m = 0, g = 1, k = 3.2, lower.tail = TRUE,
  log.p = FALSE)

ltmlogisst(p, m = 0, g = 1, lower.tail = TRUE, log.p = FALSE)

```

```
rtmlogisst(p, m = 0, g = 1, lower.tail = TRUE, log.p = FALSE)
```

```
eslogisst(p, m = 0, g = 1, lower.tail = TRUE, log.p = FALSE)
```

Arguments

x	vector of quantiles.
m	numeric. a central parameter (also used in model K1, K2, K3 and K4).
g	numeric. a scale parameter (also used in model K1, K2, K3 and K4).
log	boolean.
q	vector of quantiles.
lower.tail	logical. If TRUE, use p. If FALSE, use 1-p.
log.p	logical. If TRUE, probabilities p are given as log(p).
p	vector of probabilities.
n	number of observations. If length(n) > 1, the length is taken to be the number required.
k	numeric. The tail parameter, preferably strictly positive. Can be a vector (see details).
lp	vector of logit of probabilities.

Details

dlogisst function (log is available) is defined for x in (-Inf, +Inf) by:

$$dlogisst(x, m, g) = stats :: dlogis(x, location = m, scale = g * \sqrt{3}/\pi)$$

plogisst function is defined for q in (-Inf, +Inf) by:

$$plogisst(q, m, g) = stats :: plogis(q, location = m, scale = g * \sqrt{3}/\pi)$$

qlogisst function is defined for p in (0, 1) by:

$$qlogisst(p, m, g) = stats :: qlogis(p, location = m, scale = g * \sqrt{3}/\pi)$$

rlogisst function generates n random values.

In addition to the classical formats, the prefixes dp, dq, l, dl, ql are also provided:

dplogisst function (log is available) is defined for p in (0, 1) by:

$$dplogisst(p, m, g) = p * (1 - p) / g * \pi / \sqrt{3} + m * 0$$

dqlogisst function (log is available) is defined for p in (0, 1) by:

$$dqlogisst(p, m, g) = 1/p/(1 - p) * \sqrt{3}/\pi * g + m * 0$$

llogisst function is defined for x in (-Inf, +Inf) by:

$$llogisst(x, m, g) = (x - m) / g * \pi / \sqrt{3}$$

dllogisst function is defined for $lp = \text{logit}(p)$ in $(-\text{Inf}, +\text{Inf})$ by :

$$dllogisst(lp, m, g) = p * (1 - p) / g * pi / sqrt(3)$$

qllogisst function is defined for $lp = \text{logit}(p)$ in $(-\text{Inf}, +\text{Inf})$ by :

$$qllogisst(lp, m, g) = m + sqrt(3) / pi * g$$

If k is a vector, then the use of the function `outer` is recommended.

Functions `eslogis` is the expected shortfall of the logistic function (times a factor 2). When $p \leq 0.5$, it is equivalent (times -1) to the left tail mean `ltmlogisst`. When $p > 0.5$, it is equivalent to the right tail mean `rtmlogisst`. `ltmlogisst` and `rtmlogisst` are used to calculate the h parameter in `hkiener1`, `hkiener2`, `hkiener3`, `hkiener4`.

Kiener distribution K1 `kiener1` which has location (m) and scale (g) parameters.

logit	<i>Logit and Invlogit Functions</i>
-------	-------------------------------------

Description

The `logit` and `invlogit` functions, widely used in this package, are wrappers of `qlogis` and `plogis` functions.

Usage

```
logit(p)
```

```
invlogit(x)
```

Arguments

<code>p</code>	numeric. one value or a vector between 0 and 1.
<code>x</code>	numeric. one value or a vector of numerics.

Details

`logit` function is defined for p in $(0, 1)$ by:

$$\text{logit}(p) = \log(p / (1 - p))$$

`invlogit` function is defined for x in $(-\text{Inf}, +\text{Inf})$ by:

$$\text{invlogit}(x) = \exp(x) / (1 + \exp(x)) = \text{plogis}(x)$$

Examples

```
logit( c(ppoints(11, a = 1), NA, NaN) )
invlogit( c(-Inf, -10:10, +Inf, NA, NaN) )
```

mData	<i>Datasets dfData, mData, tData, xData, zData, extractData : mData</i>
-------	---

Description

A list of datasets in data.frame, matrix, timeSeries, xts and zoo formats. This is the matrix format. Visit [extractData](#) for more information.

pk2pk	<i>Global Conversion Function Between Kiener Distribution Parameters</i>
-------	--

Description

A conversion function between Kiener distribution parameters $K1(m, g, k)$, $K2(m, g, a, w)$, $K3(m, g, k, d)$ and $K4(m, g, k, e)$ to and from $\text{coefk} = c(m, g, a, k, w, d, e)$ extracted from [regkienerLX](#) and [paramkienerX](#).

Usage

```
pk2pk(coefk, model = "K2", to = "K7", dgts = NULL)
```

Arguments

coefk	vectors of numeric of length 3, 4 or 7.
model	character. Either "K1", "K2", "K3", "K4", "K7".
to	character. Either "K1", "K2", "K3", "K4", "K7".
dgts	integer. The rounding applied to the output.

Details

Kiener distributions use the following parameters, some of them being redundant. See also [aw2k](#) for the formulas and the conversion between parameters:

- m (μ) is the median of the distribution,.
- g (γ) is the scale parameter.
- a (α) is the left tail parameter.
- k (κ) is the harmonic mean of a and w and describes a global tail parameter.
- w (ω) is the right tail parameter.
- d (δ) is the distortion parameter.
- e (ϵ) is the eccentricity parameter.

pk2pk() performs the conversion between the various representation, from and to:

- "K1": $\text{kiener1}(m, g, k)$

- "K2": kiener2(m, g, a, w)
- "K3": kiener3(m, g, k, d)
- "K4": kiener4(m, g, k, e)
- "K7": c(m, g, a, k, w, d, e)

coefk can take any of the above form. When length(coefk) is 4, model = "K2", "K3" or "K4" is required to differentiate the three models. When length(coefk) is 3 or 7, recognition is automatic and model = "K1" or "K7" is ignored. The vector is assumed to be correct and there is no check of the consistency between the parameters a, k, w, d and e.

The output may be any of the above forms. Default is "K7" = c(m, g, a, k, w, d, e) which is coefk provided by the regression function [regkienerLX](#) or the parameter estimation function [paramkienerX](#). It is widely in many plots.

An integer rounding parameter is provided through dgts. Default is no rounding.

regkienerLX

Regression Function for Kiener Distributions

Description

One function to estimate the parameters of Kiener distributions K1, K2, K3 and K4 and display the results in a list with many `data.frame` ready to use for plotting. This function performs an unweighted nonlinear regression of the logit of the empirical probabilities `logit(p)` on the quantiles `X`.

Usage

```
regkienerLX(X, model = "K4", pdgts = c(3, 3, 1, 1, 1, 3, 2, 4, 4, 2, 2),
  maxk = 10, mink = 0.2, app = 0, probak = pprobs2, dgts = NULL,
  exfitk = NULL)
```

Arguments

<code>X</code>	vector of quantiles.
<code>model</code>	the model used for the regression: "K1", "K2", "K3", "K4".
<code>pdgts</code>	vector of length 11. Control the rounding of output parameters.
<code>maxk</code>	numeric. The maximum value of tail parameter <code>k</code> .
<code>mink</code>	numeric. The minimum value of tail parameter <code>k</code> .
<code>app</code>	numeric. The parameter "a" in the function <code>ppoints</code> .
<code>probak</code>	vector of probabilities used in output <code>regk\$fitk</code> . For instance pprobs0 .
<code>dgts</code>	rounding parameter applied globally to output <code>regk\$fitk</code> .
<code>exfitk</code>	character. A vector of parameter names to subset <code>regk\$fitk</code> . For instance exfit0 .

Details

This function is designed to estimate the parameters of Kiener distributions for a given dataset. It encapsulates the four distributions described in this package. "K1" uses model `lqkiener1`, "K2" uses model `lqkiener2`, "K3" uses model `lqkiener3` and "K4" uses model `lqkiener4`.

A typical input is a numeric vector that describes the returns of a stock. Conversion from a (possible) time series format to a sorted numeric vector is done automatically and without any check of the initial format. There is also no check of missing values, Na, NaN, -Inf, +Inf. Empirical probabilities of each point in the sorted dataset is calculated with the function `ppoints`. The parameter `app` corresponds to the parameter `a` in `ppoints` but has been limited to the range (0, 0.5). Default value is 0 as large datasets are very common in finance.

A nonlinear regression is performed with `nlsLM` from the logit of the probabilities $\text{logit}(p)$ over the quantiles `X` with one of the functions `lqkiener1234`. These functions have been selected as they have an explicit form in the four types (this is unfortunately not the case for `dkkiener234`) and return satisfactory results with ordinary least squares. The median is calculated before the regression and is injected as a mandatory value in the regression function.

Kiener distributions use the following parameters, some of them being redundant. See `aw2k` and `pk2pk` for the formulas and the conversion between parameters:

- `m` (`mu`) is the median of the distribution.
- `g` (`gamma`) is the scale parameter.
- `a` (`alpha`) is the left tail parameter.
- `k` (`kappa`) is the harmonic mean of `a` and `w` and describes a global tail parameter.
- `w` (`omega`) is the right tail parameter.
- `d` (`delta`) is the distortion parameter.
- `e` (`epsilon`) is the eccentricity parameter.

Where:

- `c(m, g, k)` of length 3 for distribution "K1".
- `c(m, g, a, w)` of length 4 for distribution "K2".
- `c(m, g, k, d)` of length 4 for distribution "K3".
- `c(m, g, k, e)` of length 4 for distribution "K4".
- `c(m, g, a, k, w, d, e)` of length 7 extracted from object of class `c1regk` like `regkienerLX` (typically `"reg$coefk"`).

Model "K1" return results with 1+2=3 parameters and describes a (assumed) symmetric distribution. Parameters `d` and `e` are set to 0. Models "K2", "K3" and "K4" describe asymmetric distributions. They return results with 1+3=4 parameters. Model "K2" has a very clear parameter definition but unfortunately parameters `a` and `w` are highly correlated. Model "K3" has the least correlated parameters but the meaning of the distortion parameter `d`, usually of order $1e-3$, is not simple.

Model "K4" exhibits a reasonable correlation between each parameter and should be the preferred intermediate model between "K1" and "K2" models. The eccentricity parameter `e` is well defined and easy to understand: $e = (a - w)/(a + w)$, $a = k/(1 - e)$ and $w = k/(1 + e)$. It varies between -1 and +1 and can be understood as a percentage (if times 100) of eccentricity. `e = -1` corresponds

to $w = \text{infinity}$, $e = +1$ corresponds to $a = \text{infinity}$ and the model becomes a single log-logistic function with a right / left stopping point and a left / right tail.

Tail parameter lower and upper values are controlled by `maxk` and `mink`. An upper value $maxk = 10$ is appropriate for datasets of low and medium size, less than 50.000 points. For larger datasets, the upper limit can be extended up to $maxk = 20$. Such a limit returns results which are very closed to the logistic distribution, an alternate distribution which could be more appropriate. The lower limit `mink` is intended to avoid the value $k = 0$. Remind that value $k < 2$ describes distribution with no stable variance and $k < 1$ describes distribution with no stable mean.

The output is an object in a flat format of class `clregk`. It can be listed with the function `attributes`.

- First are the data.frames with the initial data and the estimated results.
- Second is the result of the regression `regk0` given by `nlsLM` from which a few information have been extracted and listed here.
- Third are the regression parameters (without the median) in plain format (no rounding), the variance-covariance matrix, the variance-covariance matrix times $1e+6$ and the correlation matrix in a rounded format. Note that `regk0`, `coefk0`, `coefk0tt`, `vcovk0`, `mcork0` have a polymorphic format and changing parameters that depend from the selected model: "K1", "K2", "K3", "K4". They should be used with care in subsequent calculations.
- Fourth are the distribution parameters tailored to every model "K1", "K2", "K3", "K4" plus estimated quantiles at levels: `c(0.001, 0.005, 0.01, 0.05, 0.5, 0.95, 0.99, 0.995, 0.999)`. They are intended to subsequent calculations.
- Fifth are the same parameters presented in a more readable format thanks to the vector `pdgts` which controls the rounding of the parameters in the following order:
- `pdgts = c("m", "g", "a", "k", "w", "d", "e", "vcovk0", "vcovk0m", "mcork0", "quantr")`.
- Sixth are some probabilities and the corresponding estimated quantiles and estimated Expected Shortfall stored in a data.frame format.
- Last is `fitk` which returns all parameters in the same format than `fitkienerX`, eventually subsetted by `exfitk`. IMPORTANT : if you need to subset `fitk`, always subset it by parameter names and never subset it by rank number as new items may be added in the future. Use for instance `exfitk = exfit0, ..., exfit7`.

Value

<code>dfrXP</code>	data.frame. X = initial quantiles. P = empirical probabilities.
<code>dfrXL</code>	data.frame. X = initial quantiles. L = logit of probabilities.
<code>dfrXR</code>	data.frame. X = initial quantiles. R = residuals after regression.
<code>dfrEP</code>	data.frame. E = estimated quantiles. P = probabilities.
<code>dfrEL</code>	data.frame. E = estimated quantiles. L = logit of probabilities.
<code>dfrED</code>	data.frame. E = estimated quantiles. D = estimated density (from probabilities).
<code>regk0</code>	object of class <code>nls</code> extracted from the regression function <code>nlsLM</code> .
<code>coefk0</code>	the regression parameters in plain format. The median is out of the regression.
<code>vcovk0</code>	rounded variance-covariance matrix.
<code>vcovk0m</code>	rounded $1e+6$ times variance-covariance matrix.

mcork0	rounded correlation matrix.
coefk	all parameters in plain format.
coefk1	parameters for model "K1".
coefk2	parameters for model "K2".
coefk3	parameters for model "K3".
coefk4	parameters for model "K4".
quantk	quantiles of interest.
coefr	all parameters in a rounded format.
coefr1	rounded parameters for model "K1".
coefr2	rounded parameters for model "K2".
coefr3	rounded parameters for model "K3".
coefr4	rounded parameters for model "K4".
quantr	quantiles of interest in a rounded format.
dfrQkPk	data.frame. Qk = Estimated quantiles of interest. Pk = probabilities.
dfrQkLk	data.frame. Qk = Estimated quantiles of interest. Lk = Logit of probabilities.
dfrESkPk	data.frame. ESk = Estimated Expected Shortfall. Pk = probabilities.
dfrESkLk	data.frame. ESk = Estimated Expected Shortfall. Lk = Logit of probabilities.
fitk	Parameters, quantiles, moments, VaR, ES and other parameters (not rounded). Length of fitk depends on the choice applied to probak. IMPORTANT : if you need to subset fitk, always subset it by parameter names and never subset it by rank number as new items may be added in the future. Use for instance exfit0 , ..., exfit7 .

roundcoefk

Round Coefk

Description

Round coefk parameters in a standard manner or in a special manner, the latest being useful to display nice matrix or data.frame.

Usage

```
roundcoefk(coefk, dgts = NULL, parnames = TRUE)
```

Arguments

coefk	numeric, matrix or data.frame representing parameters $c(m, g, a, k, w, d, e)$.
dgts	integer. The number of rounded digits.
parnames	boolean. Output displayed with or without parameter names.

Details

For dgts between 1 and 9, rounding is done in the standard way and all parameters are rounded at the same number of digits.

For dgts between 10 and 27, rounding of parameters $c(m, g, a, k, w, d, e)$ is done in the following way:

- dgts = 10 : $c(0, 0, 1, 1, 1, 3, 2)$
- dgts = 11 : $c(1, 1, 1, 1, 1, 3, 2)$
- dgts = 12 : $c(2, 2, 1, 1, 1, 3, 2)$
- dgts = 13 : $c(3, 3, 1, 1, 1, 3, 2)$
- dgts = 14 : $c(4, 4, 1, 1, 1, 3, 2)$
- dgts = 15 : $c(5, 5, 1, 1, 1, 3, 2)$
- dgts = 16 : $c(0, 0, 2, 2, 2, 3, 2)$
- dgts = 17 : $c(1, 1, 2, 2, 2, 3, 2)$
- dgts = 18 : $c(2, 2, 2, 2, 2, 3, 2)$
- dgts = 19 : $c(3, 3, 2, 2, 2, 3, 2)$
- dgts = 20 : $c(4, 4, 2, 2, 2, 3, 2)$

- dgts = 21 : c(5, 5, 2, 2, 2, 3, 2)
- dgts = 22 : c(0, 0, 3, 3, 3, 4, 3)
- dgts = 23 : c(1, 1, 3, 3, 3, 4, 3)
- dgts = 24 : c(2, 2, 3, 3, 3, 4, 3)
- dgts = 25 : c(3, 3, 3, 3, 3, 4, 3)
- dgts = 26 : c(4, 4, 3, 3, 3, 4, 3)
- dgts = 27 : c(5, 5, 3, 3, 3, 4, 3)

Examples

```
mat <- matrix(runif(35), ncol=7)
coefk <- mat[1,]

roundcoefk(coefk, dgts = 2, parnames = FALSE)
roundcoefk(coefk, dgts = 15)

```

tData	<i>Datasets dfData, mData, tData, xData, zData, extractData : tData</i>
-------	---

Description

A list of datasets in data.frame, matrix, timeSeries, xts and zoo formats. This is the timeSeries format. Visit [extractData](#) for more information.

xData	<i>Datasets dfData, mData, tData, xData, zData, extractData : xData</i>
-------	---

Description

A list of datasets in data.frame, matrix, timeSeries, xts and zoo formats. This is the xts format. Visit [extractData](#) for more information.

zData	<i>Datasets dfData, mData, tData, xData, zData, extractData : zData</i>
-------	---

Description

A list of datasets in data.frame, matrix, timeSeries, xts and zoo formats. This is the zoo format. Visit [extractData](#) for more information.
