Package 'hydroTSM'

November 4, 2024

Type Package

Title Time Series Management and Analysis for Hydrological Modelling

Version 0.7-0.1

Maintainer Mauricio Zambrano-Bigiarini <mzb.devel@gmail.com>

Description

S3 functions for management, analysis, interpolation and plotting of time series used in hydrology and related environmental sciences. In particular, this package is highly oriented to hydrological modelling tasks. The focus of this package has been put in providing a collection of tools useful for the daily work of hydrologists (although an effort was made to optimise each function as much as possible, functionality has had priority over speed). Bugs / comments / questions / collaboration of any kind are very welcomed, and in particular, datasets that can be included in this package for academic purposes.

License GPL (>= 2)

Depends R (>= 3.5.0), zoo (>= 1.7-2)

Imports xts (>= 0.9-7), e1071, stats, utils, methods, graphics, grDevices, lattice, classInt

Suggests knitr, rmarkdown, gridExtra

VignetteBuilder knitr

Details

Package:	hydroTSM
Type:	Package
Version:	0.7-0
Date:	2024-01-14
License:	$GPL \ge 2$
LazyLoad:	yes
Packaged:	Wed 17 Jan 2024 20:43:17 -03 ; MZB
BuiltUnder:	R version 4.3.2 (2023-10-31) ;x86_64-pc-linux-gnu (64-bit)

Datasets:

Cauquenes7336001 Hydrometeorological time series for "Cauquenes en El Arrayan" catchment. EbroPPtsMonthly Ebro Monthly Precipitation Time Series. KarameaAtGorgeQts Karamea at Gorge, time series of hourly streamflows. MaquehueTemuco San Martino, ts of daily precipitation. OcaEnOnaQts Oca in "Ona" (Q0931), time series of daily streamflows SanMartinoPPts San Martino, ts of daily precipitation. Temporal aggregation:

annualfunction single representative annual value of a zoo object. weeklyfunction single representative weekly value of a zoo object. monthlyfunction single representative monthly value of a zoo object. seasonal function representative values of each weather season of a zoo object. daily2annual Aggregation from daily to annual subdaily2annual Aggregation from subdaily to annual. monthly2annual Aggregation from monthly to annual. daily2monthly Aggregation from daily to monthly. subdaily2monthly Aggregation from subdaily to monthly. daily2weekly Aggregation from daily to weekly. dm2seasonal Aggregation from daily or monthly to seasonal. subdaily2seasonal Aggregation from subdaily to seasonal. subdaily2daily Aggregation from subdaily to daily. subdaily2weekly Aggregation from subdaily to weekly. subhourly2hourly Aggregation from subhourly to hourly. subhourly2nminutesAggregation from subhourly to n-minutes.

Temporal manipulation:

dip Days in period. diy Days in year. hip Hours in period. mip Months in period. yip Years in period. izoo2rzoo Irregular zoo object to regular zoo objectl. time2season Time to weather season. vector2zoo Numeric and date/times to zoo object.

Hydrological functions:

baseflow Baseflow computation. climograph Climograph dwdays Dry and wet days. fdc Flow duration curve. fdcu Flow duration curve with uncertainty bounds. hydroplot Exploratory figure for hydrological time series. sname2plot Hydrological time series plotting and extraction. plot_pq Plot precipitation and streamflow time series in the same figure. si Seasonality Index for precipitation. sname2ts Station Name -> Time Series. zoo2RHtest Zoo object -> RHTest. Miscelaneous functions:

calendarHeatmap Calendar heat map. cmv Counting missing values. drawxaxis Draw a temporal horizontal axis. dwi Days with information. extract Extract a subset of a zoo object. hydropairs Visual correlation matrix. infillxy Infills NA values. istdx Inverse standarization. ma Moving average. matrixplot 2D color matrix. rm1stchar Remove first character. sfreq Sampling frequency. smry Improved summary function. stdx Standarization.

Examples

Loading the monthly time series (10 years) of precipitation for the Ebro River basin. data(EbroPPtsMonthly)

#######

```
## Ex1) Graphical correlation among the ts of monthly precipitation of the first
## 3 stations in 'EbroPPtsMonthly' (its first column stores the dates).
hydropairs(EbroPPtsMonthly[,2:4])
```

#######

#######

Ex3) Monthly and annual plots
sname2plot(EbroPPtsMonthly, sname="P9001", var.type="Precipitation", pfreq="ma")

```
#######
## Ex5) Mean monthly values of streamflows
## Loading daily streamflows (3 years) at the station
## Oca en Ona (Ebro River basin, Spain)
data(OcaEnOnaQts)
monthlyfunction(OcaEnOnaQts, FUN=mean, na.rm=TRUE)
```

(sub)daily2annual (sub)Daily/Monthly -> Annual

Description

Generic function for transforming a (sub)DAILY/MONTHLY (weekly and quarterly) regular time series into an ANNUAL one.

Usage

Arguments

zoo, data.frame or matrix object, with (sub)daily/monthly time series. Measurements at several gauging stations can be stored in a data.frame or matrix object, and in that case, each column of x represents the time series measured in each gauging station, and the column names of x have to correspond to the ID of each station (starting by a letter).

Х

FUN	Function that have to be applied for aggregating from (sub)daily/monthly into annual time step (e.g., for precipitation FUN=sum and for temperature and stream-flows ts FUN=mean).
	FUN MUST accept the na.rm argument, because na.rm is passed to FUN.
	When FUN=max or FUN=min the date(time) where the maximum/minimum value actually occurs is returned in the output object, otherwise, a generic 1st of january for each year is returned.
na.rm	Logical. Should missing values be removed? -) TRUE : the annual values are computed only for years with a percentage of missing values less than na.rm.max -) FALSE: if there is AT LEAST one NA within a year, the corresponing annual values in the output object will be NA.
na.rm.max	Numeric in [0, 1]. It is used to define the maximum percentage of missing values allowed in each year to keep the yearly aggregated value in the output object of this function. In other words, if the percentage of missing values in a given year is larger or equal than na.rm.max the corresponding annual value will be NA.
out.fmt	Character indicating the date format for the output zoo object. See format in as.Date. Possible values are: -) %Y : only the year will be used for the time. Default option. (e.g., "1961" "1962") -) %Y-%m-%d: a complete date format will be used for the time. (e.g., "1961-01- 01" "1962-01-01"). See Details.
dates	numeric, factor or Date object indicating how to obtain the dates for correspond- ing to each gauging station If dates is a number (default), it indicates the index of the column in x that stores the dates If dates is a factor, it is converted into Date class, using the date format speci- fied by date.fmt If dates is already of Date class, the code verifies that the number of days on it be equal to the number of element in x
date.fmt	character indicating the format in which the dates are stored in <i>dates</i> , e.g. %Y-%m-%d. See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric".
out.type	 Character that defines the desired type of output. Valid values are: -) data.frame: a data.frame, with as many columns as stations are included in x, and row names indicating the Year -) db : a data.frame, with 3 columns will be produced. The first column (StationID) will store the ID of the station The second column (Year) will store the year, The third column (Value) will contain the annual value corresponding to the two previous columns.
verbose	logical; if TRUE, progress messages are printed
	arguments additional to na.rm passed to FUN.

8

When FUN!=max and FUN!=min the output is a zoo object with annual time frequency, where the time attribute has the format defined in out.fmt.

When FUN!=max and FUN!=min and out.fmt="%Y-%m-%d" the time attribute of the output zoo object will use the 1st of January of each year to create a full Date object from the corresponding year of each element of the output object (e.g., fi the year is 2022, the time attribute will be 2022-01-01). The only exception occurrs when FUN=max or FUN=min, where the time attribute of each element will correspond to the actual date where the annual maximum/minimum occurs (which is very useful for identifying the date of the annual maximum or the annual minimum of a time series).

When FUN=max or FUN=min and x is a single time series, the output is a zoo object with annual time frequency, where the time attribute has the same class than time(x), and the date(time) value corresponds to the date(time) where the maximum/minimum value actually occurs.

When FUN=max or FUN=min and x has two or more time series, the output is a list object where each element has an annual time frequency. The time attribute of each list element has the same class than time(x), and the date(time) value of each list element corresponds to the date(time) where the maximum/minimum value actually occurs.

na.index
          <- sample(1:n, n.nas)
x[na.index] <- NA
```

Daily to annual, only for months with less than 10% of missing values (a2 <- daily2annual(x, FUN=sum, na.rm=TRUE, na.rm.max=0.1))

Verifying that the second and third month of 'x' had 10% or more of missing values cmv(x, tscale="annual")

Ex3: Getting the annual maximum value, including the date where this annual ## maximum actually occurs daily2annual(x, FUN=max)

Ex4: Monthly to Annual (same result as)
m <- daily2monthly(x, FUN=sum, na.rm=TRUE)
monthly2annual(m, FUN=sum, na.rm=TRUE)</pre>

Ex5: Loading the time series of HOURLY streamflows for the station Karamea at Gorge
data(KarameaAtGorgeQts)
x <- KarameaAtGorgeQts</pre>

Sub-daily to monthly ts
subdaily2annual(x, FUN=mean, na.rm=TRUE)

############

Ex6: Loading the monthly time series of precipitation within the Ebro River basin data(EbroPPtsMonthly)

computing the annual values for the first 10 gauging stations in 'EbroPPtsMonthly' a <- monthly2annual(EbroPPtsMonthly[,1:11], FUN=sum, dates=1)</pre>

same as before, but with a nicer format of years

a <- monthly2annual(EbroPPtsMonthly[,1:11], FUN=sum, dates=1, out.fmt="%Y")</pre>

(sub)daily2monthly (sub)Daily -> Monthly

Description

Generic function for transforming a DAILY (sub-daily or weekly) regular time series into a MONTHLY one

Usage

Arguments

x	zoo, data.frame or matrix object, with (sub)daily time series. Measurements at several gauging stations can be stored in a data.frame or matrix object, and in that case, each column of x represents the time series measured in each gauging station, and the column names of x have to correspond to the ID of each station (starting by a letter).
FUN	Function that have to be applied for transforming from daily to monthly time step (e.g., for precipitation FUN=sum and for temperature and streamflow ts FUN=mean).
	FUN MUST accept the na.rm argument, because na.rm is passed to FUN.
na.rm	 Logical. Should missing values be removed? -) TRUE : the monthly values are computed only for months with a percentage of missing values less than na.rm.max -) FALSE: if there is AT LEAST one NA within a month, the corresponding monthly values in the output object will be NA.

10

na.rm.max	Numeric in [0, 1]. It is used to define the maximum percentage of missing values allowed in each month to keep the monthly aggregated value in the output object of this function. In other words, if the percentage of missing values in a given month is larger or equal than na.rm.max the corresponding monthly value will be NA.
dates	 numeric, factor or Date object indicating how to obtain the dates for each gauging station If dates is a number (default), it indicates the index of the column in x that stores the dates If dates is a factor, it is converted into Date class, using the date format specified by date.fmt If dates is already of Date class, the code verifies that the number of days on it be equal to the number of elements in x
date.fmt	character indicating the format in which the dates are stored in <i>dates</i> , e.g. %Y-%m-%d. See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric".
out.type	 Character that defines the desired type of output. Valid values are: -) data.frame: a data.frame, with as many columns as stations are included in x, and row names indicating the month and year for each value. -) db : a data.frame, with 4 columns will be produced. The first column (StationID) stores the ID of the station, The second column (Year) stores the year The third column (Month) stores the Month The fourth column (Value) stores the numerical values corresponding to the values specified in the three previous columns.
out.fmt	OPTIONAL. Only used when x is a matrix or data.frame object /cr character, for selecting if the result will be a matrix/data.frame or a zoo object. Valid values are: numeric, zoo.
verbose	logical; if TRUE, progress messages are printed
	arguments additional to na.rm passed to FUN.

Value

a zoo object with monthly time frequency

12

annualfunction

Annual Function

Description

Generic function for obtaining a SINGLE annual value of a zoo object, by applying any R function to ALL the values in x belonging to the same year, and then applying the same function to ALL the previously computed annual values (e.g., for computing the average annual precipitation or the mean annual streamflow of a long-term time series).

Usage

```
annualfunction(x, FUN, na.rm = TRUE, ...)
## Default S3 method:
annualfunction(x, FUN, na.rm = TRUE, ...)
## S3 method for class 'zoo'
annualfunction(x, FUN, na.rm = TRUE, ...)
## S3 method for class 'data.frame'
annualfunction(x, FUN, na.rm = TRUE, dates=1, date.fmt = "%Y-%m-%d",
            verbose = TRUE, ...)
## S3 method for class 'matrix'
annualfunction(x, FUN, na.rm = TRUE, dates=1, date.fmt = "%Y-%m-%d",
            verbose = TRUE, ...)
```

Arguments

x	zoo, xts, data.frame or matrix object, with daily/monthly/annual time series. Measurements at several gauging stations can be stored in a data.frame of matrix object, and in that case, each column of x represent the time series measured in each gauging station, and the column names of x have to correspond to the ID of each station (starting by a letter).
FUN	Function that will be used to compute the final annual value (e.g., FUN may be some of mean, sum, max, min, sd) .
na.rm	Logical. Should missing values be removed?. -) TRUE : the annual values are computed considering only those values different from NA -) FALSE: if there is AT LEAST one NA within a year, the resulting annual value will be NA
dates	numeric, factor or Date object indicating how to obtain the dates corresponding to each gauging station. If dates is a number (default), it indicates the index of the column in x that stores the dates

	If dates is a factor, it have to be converted into Date class, using the date format specified by date.fmt If dates is already of Date class, the code verifies that the number of days in dates be equal to the number of elements in x
date.fmt	character indicating the format in which the dates are stored in <i>dates</i> , e.g. %Y-%m-%d. See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric".
verbose	Logical; if TRUE, progress messages are printed.
	further arguments passed to or from other methods.

Value

When x is a time series, a single annual value is returned. For a data frame, a named vector with the appropriate method being applied column by column.

Note

FUN is first applied to all the values of x belonging to the same year and then it is applied to all the previously computed annual values to get the final result. Its result will depend on the sampling frequency of x and the type of function provided by FUN (**special attention have to be put when** FUN=sum)

annualfunction(z[ ,1:5], FUN=sum)/nyears
## End(Not run)
```

baseflow

Baseflow

Description

Given a complete (without missing values) series of streamflow, this function computes the baseflow using the filter proposed by Arnold and Allen (1999).

Usage

Arguments

x	zoo or numeric object with streamflow records. The suggested time frequency should be hourly or daily, but the algorithm will work with any time frequency.
beta	numeric representing the filter parameter. Default value is 0.925 as recommended by Arnold and Allen (1999)
from	Character indicating the starting date for subsetting x. It has to be in the format indicated by date.fmt. The default value corresponds to the date of the first element of x.
to	Character indicating the ending date for subsetting x. It has to be in the format indicated by date.fmt. The default value corresponds to the date of the last element of x.
date.fmt	character indicating the format in which the dates are stored in from and to, e.g. %Y-%m-%d. See 'Details' section in strptime. By default, date.fmt is missing, and it is automatically set to %Y-%m-%d when time(x) is Date object, and set to %Y-%m-%d %H:%M:%S when x is a sub-daily zoo object.
tz	character, with the specification of the time zone used for from, to. System- specific (see time zones), but "" is the current time zone, and "GMT" is UTC (Universal Time, Coordinated). See Sys.timezone and as.POSIXct.
	If tz is missing (the default), it is automatically set to the time zone used in $time(x)$.
	This argument can be used when working with sub-daily zoo objects to force using time zones other than the local time zone for from and to. It should be used with caution, being well aware of the time zone of the data. See examples.
na.fill	 Character indicating how to fill any NA present in x. Valid values are: -) remove => NAs are not plotted -) linear => NAs are removed by linear interpolation, using na.approx -) spline => NAs are removed by spline interpolation, using na.spline
out.type	Character indicating the type of result that is given by this function. Valid values
	are: -) last => only the baseflow computed after the third pass of the filter is re- turned.
	-) all => the 3 baseflows computed after each pass of the filter are returned in a matrix or zoo object.
plot	logical. Indicates if the baseflow should be plotted or not. If plotted, the original x values are plotted as well.
xcol	character, representing the color to be used for ploting the streamflow time series. Only used when plot=TRUE.
bfcol	character of lenght 3, representing the color(s) to be used for ploting the base- flow time series. The first, second and third element are used to represent the baseflow after the third, second and first pass of the filter, respectively. Only used when plot=TRUE.
pch	numeric, representing the symbols used for ploting the streamflow time series (both, the original series and the baseflow). Only used when plot=TRUE.

baseflow

cex	a numerical vector giving the amount by which plotting characters and symbols should be scaled relative to the default. This works as a multiple of par("cex"). See plot.default. Only used when plot=TRUE.
	further arguments passed to or from other methods. Not used yet.

Details

Although most procedures to separate baseflow from total streamflow are based on physical reasoning, some elements of all separation techniques are subjective.

The digital filter technique (Nathan and McMahon, 1990) implemented in this function was originally proposed by Lyne and Hollick (1979) for signal analysis and processing. Although this technique has no true physical meaning, it is objective and reproducible.

The equation of the filter is:

 $q(t) = Beta^{*}q(t-1) + [(1+Beta)/2]^{*}[Q(t) - Q(t-1)]$

where q(t) is the filtered surface runoff (quick response) at the time step t (one day), Q is the original streamflow, and Beta is the filter parameter (Beta=0.925). The value Beta=0.925 was obtained by Nathan and McMahon (1990) and Arnold et al. (1995) to give realistic results when compared to manual separation techniques.

Baseflow b(t) is then computed as:

 $\mathbf{b}(\mathbf{t}) = \mathbf{Q}(\mathbf{t}) - \mathbf{q}(\mathbf{t})$

The filter can be passed over the streamflow data three times (forward, backward, and forward), depending on the user' selected estimates of baseflow from pilot studies. In general, each pass will result in less baseflow as a percentage of total streamflow.

Value

If out.type="last"

(default value), only the baseflow computed after the third pass of the filter is returned.

If out.type="all"

the 3 baseflows computed after each pass of the filter are returned in a matrix or zoo object.

calendarHeatmap Calendar heatmap

Description

Function to plot a heatmap of a daily zoo object with a calendar shape

calendarHeatmap

Usage

```
calendarHeatmap(x, ...)
## S3 method for class 'zoo'
calendarHeatmap(x, from, to, date.fmt="%Y-%m-%d",
    main="Calendar Heat Map",
    col=colorRampPalette(c("red", "orange", "yellow", "white",
            "lightblue2", "deepskyblue", "blue3"), space = "Lab")(8),
    cuts, cuts.dec=0, cuts.labels,
    cuts.style=c("fisher", "equal", "pretty", "fixed", "sd",
                  "quantile", "kmeans", "bclust", "mzb"),
    legend.title="", legend.fontsize=15,
    do.png=FALSE, png.fname="mypng.png", png.width=1500,
    png.height=900, png.pointsize=12, png.res=90,
    do.pdf=FALSE, pdf.fname="mypdf.pdf", pdf.width=11,
    pdf.height=8.5, pdf.pointsize=12, ...)
```

Arguments

x	daily zoo object to be plotted. Its maximum amount of daily data should be less than 6 years or otherwise it will not be plotted.
from	Character indicating the starting date for subsetting x. It has to be in the format indicated by date.fmt.
to	Character indicating the ending date for subsetting x . It has to be in the format indicated by date.fmt.
date.fmt	character indicating the format in which the dates are stored in from and to, e.g. %Y-%m-%d. See 'Details' section in strptime.
main	character, Main chart title.
col	A color palette, i.e. a vector of n contiguous colors generated by functions like rainbow, heat.colors, topo.colors, bpy.colors or one of your own making, perhaps using colorRampPalette. If none is provided, a color ramp with 8 colours is created using colorRampPalette.
cuts	Numeric, indicating the values used to divide the range of x in the legend of colours. If not provided, it is automatically selected as a function of lenght(col).
cuts.dec	Number of decimal places used to present the numbers in the legend of colours.
cuts.labels	Character indicating the label to be used in the colour legend for each one of the values defined by cuts. If not provided, as.character(cuts) is used.
cuts.style	discarded because takes too much time or not alway provide the required number of classes: "dpih", "headtails", "hclust", "jenks".
legend.title	text to be displayed above the legend of colours.
legend.fontsize	2
	size of text (in points) used in the legend of colours.
do.png	Do you want to write the figure as a .png file? logical, set TRUE to save the image.

png.fname	character, indicating the name of the file (possibly with a meaninful file exten- sion) that will be used to write the output file.
png.width	numeric, the width of the device.
png.height	numeric, the height of the device.
png.pointsize	integer, the default point size of plotted text, interpreted as big points (1/72 inch) at res ppi.
png.res	integer, the nominal resolution in ppi which will be recorded in the bitmap file, if a positive integer. Also used for units other than the default, and to convert points to pixels.
do.pdf	Do you want to write the figure as a .pdf file? logical, set TRUE to save the image.
pdf.fname	character, indicating the name of the file (possibly with a significant extension) that will be used to write the output file.
pdf.width	numeric, the width of the device.
pdf.height	numeric, the height of the device.
pdf.pointsize	integer, the default point size to be used. Strictly speaking, in bp, that is 1/72 of an inch, but approximately in points. Defaults to 12.
	further arguments passed to functions or from other methods. Not used yet.

Details

The original function calendarHeat was developed by Paul Bleicher, as an R version of a graphic from http://stat-computing.org/dataexpo/2009/posters/wicklin-allison.pdf (not available any longer). The original function was made available online in 2009, but then it was removed. Now it is available at https://github.com/tavisrudd/r_users_group_1/blob/master/calendarHeat.R. The original function has "Copyright 2009 Humedica", but it was distributed under the GPL-2 licence, as well as this new version of the function.

This slighly modified verison of the function is also distributed under the GPL-2 licence, and teh main changes with respect to the original function are:

1) uses a zoo object instead of a numeric and character vector, for values and dates, respectively.

2) it allows a customisation of the mian title of the output figure.

3) it allows a customisation of the color palette.

4) it uses a categorical legend instead of a continuos one.

5) it is named calendarHeatmap instead of calendarHeat.

Value

The output of this function is a lattice figure with the calendar heatmap

Note

The maximum amount of years to be plotted is six (6).

Cauquenes7336001	Hydrometeorological	time series	s for	"Cauquenes	en	El	Arrayan"
	catchment						

Description

Daily time series of precipitation, maximum air temperature, minimum air temperature, potential evapotranspiration, and observed streamflows for the catchment draining into the 'Cauquenes en El Arrayan' streamflow station (Cod.BNA: 7336001, Lat:-36.02, Lon:-72.38). This catchment is located in El Maule Region in Chile, with a pluvial regime, a total drainage area of 622.1 km2, and elevations ranging from 134 to 736 m a.s.l. Data were downloaded from the CAMELS-CL dataset (https://camels.cr2.cl) from 01/Jan/1979 to 31/Dec/2019 (including some missing values).

Usage

```
data(Cauquenes7336001)
```

Format

zoo matrix with 5 time series:

-) *P_mm*: Spatially-averaged mean daily values of precipitation computed based on the CR2met dataset, [mm/day].

-) *Tmx_degC*: Spatially-averaged maximum daily values of air temperature computed based on the CR2met dataset, [degree Celsius].

-) *Tmin_degC*: Spatially-averaged minimum daily values of air temperature computed based on the CR2met dataset, [degree Celsius].

-) *PET_mm*: Spatially-averaged mean daily values of precipitation computed based on the Hargreaves-Samani equation and daily maximum and minimum air temperatures obtained from the CR2met dataset, [mm/day].

-) *Qobs_mm*: Daily sreamflows, [mm], measured at the "Cauquenes en El Arrayan" (7336001) station.

-) *Qobs_m3s*: Daily sreamflows, [m3/s], measured at the "Cauquenes en El Arrayan" (7336001) station.

climograph Climograph

Description

Function to draw a climograph based on precipitation and air temperature data, with several options for customisation.

Usage

```
plot.temp.probs=TRUE, temp.probs=c(0.25, 0.75),
temp.probs.col=c("#3399FF", "#FF9966", "#FFCC66"),
temp.probs.alpha=0.3,
lat, lon
)
```

Arguments

рср	variable of type zoo with monthly, daily or subdaily precipitation data.
tmean	variable of type 'zoo' with monthly, daily or subdaily mean temperature data.
tmx	variable of type 'zoo' with monthly, daily or subdaily maximum temperature data. ONLY used (together with tmn) when tmean' is missing.
tmn	variable of type 'zoo' with monthly, daily or subdaily minimum temperature data. ONLY used (together with tmx) when tmean is missing.
na.rm	Logical. Should missing values be removed? -) TRUE : the monthly values are computed considering only those values differ- ent from NA -) FALSE: if there is AT LEAST one NA within a month, the resulting average monthly value is NA.
from	OPTIONAL, used for extracting a subset of values. Character indicating the starting date for the values to be extracted. It must be provided in the format specified by date.fmt.
to	OPTIONAL, used for extracting a subset of values. Character indicating the ending date for the values to be extracted. It must be provided in the format specified by date.fmt.
date.fmt	Character indicating the format in which the dates are stored in <i>dates</i> , <i>from</i> and <i>to</i> . See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric".
main	Character representing the main title of the plot.
pcp.label	Character used in the legend to represent the monthly average precipitation (mostly thought for languages different from English).
tmean.label	Character used in the legend to represent the monthly average temperature (mostly thought for languages different from English).
start.month	[OPTIONAL]. Only used when the (hydrological) year of interest is different from the calendar year. numeric in [1:12] indicating the starting month of the (hydrological) year. Numeric values in [1, 12] represents months in [January, December]. By default
	<pre>start.month=1.</pre>
pcp.solid.thr	[OPTIONAL]. Only used when using (sub)daily precipitation and temperature are gives as input data. numeric, indicating the temperature, in degrees Celsius, used to discriminate be- tween solid and liquid precipitation.

When daily tmean <= pcp.solid.thr the precipitation for that day is considered as solid precipitation.	
axis. The second value should be larger than the first one.temp.ylim[OPTIONAL] numeric of length 2 with the the range used for the secondary temperature axis. The second value should be larger than the first one.pcp.colColor used in the legend to represent the monthly average precipitation.pcp.solid.colColor used in the legend to represent the monthly average solid precipitation.tmean.colColor used in the legend to represent the monthly average temperature.tmn.colColor used in the legend to represent the monthly minimum temperature.tmx.colColor used in the legend to represent the monthly minimum temperature.pcp.labelslogical. Should monthly precipitation values to be shown above the bars?. By default pcp.labels=TRUE.	
temperature axis. The second value should be larger than the first one.pcp.colColor used in the legend to represent the monthly average precipitation.pcp.solid.colColor used in the legend to represent the monthly average solid precipitation.tmean.colColor used in the legend to represent the monthly average temperature.tmn.colColor used in the legend to represent the monthly minimum temperature.tmx.colColor used in the legend to represent the monthly minimum temperature.tmx.colColor used in the legend to represent the monthly maximum temperature.pcp.labelslogical. Should monthly precipitation values to be shown above the bars?. By default pcp.labels=TRUE.	
pcp.solid.colColor used in the legend to represent the monthly average solid precipitation.tmean.colColor used in the legend to represent the monthly average temperature.tmn.colColor used in the legend to represent the monthly minimum temperature.tmx.colColor used in the legend to represent the monthly maximum temperature.pcp.labelslogical. Should monthly precipitation values to be shown above the bars?. By default pcp.labels=TRUE.	
tmean.colColor used in the legend to represent the monthly average temperature.tmn.colColor used in the legend to represent the monthly minimum temperature.tmx.colColor used in the legend to represent the monthly maximum temperature.pcp.labelslogical. Should monthly precipitation values to be shown above the bars?. By default pcp.labels=TRUE.	
tmn.colColor used in the legend to represent the monthly minimum temperature.tmx.colColor used in the legend to represent the monthly maximum temperature.pcp.labelslogical. Should monthly precipitation values to be shown above the bars?. By default pcp.labels=TRUE.	
tmx.colColor used in the legend to represent the monthly maximum temperature.pcp.labelslogical. Should monthly precipitation values to be shown above the bars?. By default pcp.labels=TRUE.	
pcp.labels logical. Should monthly precipitation values to be shown above the bars?. By default pcp.labels=TRUE.	
default pcp.labels=TRUE.	
tmean.labels logical. Should monthly mean temperature values to be shown above the lines?	
By default tmean.labels=TRUE.	
<pre>tmx.labels logical. Should monthly maximum temperature values to be shown above the lines?. By default tmx.labels=TRUE.</pre>	
<pre>tmn.labels logical. Should monthly minimum temperature values to be shown above the lines?. By default tmn.labels=TRUE.</pre>	
pcp.labels.cex numeric giving the amount by which plotting characters used to show the nu- meric values of monthly precipitation values are scaled relative to the default. It is only used when pcp.labels=TRUE.	
temp.labels.cex	
numeric giving the amount by which plotting characters used to show the nu- meric values of monthly air temperature values (mean, maximum, minimum) are scaled relative to the default.	
It is only used when tmean.labels=TRUE or tmx.labels=TRUE or tmn.labels=	TRUE.
pcp.labels.dx numeric of length 12 giving the amount of horizontal coordinate positions that have to be used to shift the labels of monthly precipitation values. It is only used when pcp.labels=TRUE.	
Lengths smaller than 12 are recycled and larger lengths are not used.	
pcp.labels.dy numeric of length 12 giving the amount of vertical coordinate positions that have to be used to shift the labels of monthly precipitation values. It is only used when pcp.labels=TRUE.	
Lengths smaller than 12 are recycled and larger lengths are not used.	
temp.labels.dx numeric of length 12 giving the amount of horizontal coordinate positions that have to be used to shift the labels of monthly air temperature values (mean, maximum, minimum).	
It is only used when tmean.labels=TRUE or tmx.labels=TRUE or tmn.labels= Lengths smaller than 12 are recycled and larger lengths are not used.	
temp.labels.dy numeric of length 12 giving the amount of vertical coordinate positions that have to be used to shift the labels of monthly air temperature values (mean, maximum, minimum).	
It is only used when tmean.labels=TRUE or tmx.labels=TRUE or tmn.labels= Lengths smaller than 12 are recycled and larger lengths are not used.	TRUE.

pcp.probs numeric of length 2. It defines the quantile values used to compute the lower an upper uncertainty bounds for each one of the 12 monthly precipitation values. By default pcp.probs=c(0.25, 0.75), which indicates that the quantiles 0.25 and 0.75 are used to compute the lower an upper uncertainty bounds for each one of the 12 monthly precipitation values. If pcp is a (sub)daily zoo object, it is first aggregated into monthly values using mean, and then the pcp.probs quantiles are computed over all the monthly values belonging to a calendar month.

values of the lower an upper uncertainty bounds.

plot.temp.probs

logical used to decide whether to show uncertainty values around the monthly mean temperature values. By default plot.temp.probs=TRUE.

When plot.temp.probs=TRUE the temp.probs argument is used to define the values of the lower an upper uncertainty bounds.

temp.probs numeric of length 2. It is used to define quantile values used to compute the lower an upper uncertainty bounds for each one of the 12 monthly mean temperature values.

If tmx and tmn are provided, then temp.probs are used to compute the lower an upper uncertainty bounds for each one of the 12 monthly maximum/minimum temperature values.

By default temp.probs=c(0.25, 0.75), which indicates that the quantiles 0.25 and 0.75 are used to compute the lower an upper uncertainty bounds for each one of the 12 monthly mean(maximum/minimum) values. If tmx/tmn is provided and is a (sub)daily zoo object, it is first aggregated into monthly values using mean, and then the temp.probs quantiles are computed over all the monthly values belonging to a calendar month.

temp.probs.col character of length 3, with the colors used to for plotting the uncertainty bands around the average monthly values of the minimum, mean and maximum air temperature, respectively. If tmx and tmn are not provided by the user, the second element of temp.probs.col

will still be used to define the color of the uncertainty band around the mean monthly values of air temperature.

temp.probs.alpha

	numeric of length 1, with the factor used to modify the opacity of temp.probs.col.
	Typically in [0,1], with 0 indicating a completely transparent colour and 1 indi-
	cating no transparency.
lat	[OPTIONAL] numeric or character used to show the latitude for which the
	climograph was plotted for.

lon [OPTIONAL] numeric or character used to show the longitude for which the climograph was plotted for.

Note

If the output climograph present some mixed or not legible characters, you might try resizing the graphical window and run climograph again with the new size, until you get the climograph in the way you want to.

Counting Missing Values

Description

Generic function for counting the percentage/amount of missing values in a zoo object, using a user-defined temporal scale.

Usage

cmv(x, ...)

```
## Default S3 method:
cmv(x, tscale=c("hourly", "daily", "weekly", "monthly",
            "quarterly", "seasonal", "annual"),
            out.type=c("percentage", "amount"), dec=3,
            start="00:00:00", start.fmt= "%H:%M:%S", tz, ...)
## S3 method for class 'zoo'
cmv(x, tscale=c("hourly", "daily", "weekly", "monthly",
            "quarterly", "seasonal", "annual"),
            out.type=c("percentage", "amount"), dec=3,
            start="00:00:00", start.fmt= "%H:%M:%S", tz, ...)
## S3 method for class 'data.frame'
cmv(x, tscale=c("hourly", "daily", "weekly", "monthly",
            "quarterly", "seasonal", "annual"),
            out.type=c("percentage", "amount"), dec=3,
            start="00:00:00", start.fmt= "%H:%M:%S", tz,
            dates=1, date.fmt="%Y-%m-%d", ...)
## S3 method for class 'matrix'
cmv(x, tscale=c("hourly", "daily", "weekly", "monthly",
            "quarterly", "seasonal", "annual"),
            out.type=c("percentage", "amount"), dec=3,
            start="00:00:00", start.fmt= "%H:%M:%S", tz,
            dates=1, date.fmt="%Y-%m-%d", ...)
```

Arguments

x	zoo, data.frame or matrix object, with the time series to be analised. Measurements at several gauging stations can be stored in a data.frame or matrix object, and in that case, each column of x represents the time series measured in a gauging statio, and the column names of x have to correspond to the ID of each station (starting by a letter).
tscale	 character with the temporal scale to be used for analysing the mssing data. Valid values are: hourly: the percentage/amount of missing values will be given for each hour and ,therefore, the expected time frequency of x must be sub-hourly.) daily: the percentage/amount of missing values will be given for each day and, therefore, the expected time frequency of x must be sub-daily (i.e., hourly or sub-hourly).) weekly: the percentage/amount of missing values will be given for each week (starting on Monday) and, therefore, the expected time frequency of x must be sub-daily (i.e., daily, (sub)hourly).) monthly: the percentage/amount of missing values will be given for each month and, therefore, the expected time frequency of x must be sub-monthly (i.e., daily, hourly or sub-hourly).) quarterly: the percentage/amount of missing values will be given for each quarter and, therefore, the expected time frequency of x must be sub-quarterly (i.e., monthly, daily, hourly or sub-hourly).) seasonal: the percentage/amount of missing values will be given for each weather season (see ?time2season) and, therefore, the expected time frequency of x must be sub-quarterly of x must be sub-seasonal (i.e., monthly, daily, hourly or sub-hourly).) annual: the percentage/amount of missing values will be given for each year and, therefore, the expected time frequency of x must be sub-seasonal (i.e., monthly, daily, hourly or sub-hourly).
dec	integer indicating the amount of decimal places included in the output. It is only used when out.type=='percentage'.
start	 character, indicating the starting time used for aggregating sub-daily time series into daily ones. It MUST be provided in the format specified by start.fmt. This value is used to define the time when a new day begins (e.g., for some rain gauge stations). -) All the values of x with a time attribute before start are considered as belonging to the day before the one indicated in the time attribute of those values. -) All the values of x with a time attribute equal to start are considered to be equal to "00:00:00" in the output zoo object. -) All the values of x with a time attribute after start are considered as belonging to the same day as the one indicated in the time attribute of those values.
_	with caution. See examples.
start.fmt	character indicating the format in which the time is provided in start, By de- fault date.fmt=%H:%M:%S. See format in as.POSIXct.

cmv

tz	character, with the specification of the time zone used in both x and start. System-specific (see time zones), but "" is the current time zone, and "GMT" is UTC (Universal Time, Coordinated). See Sys.timezone and as.POSIXct. If tz is missing (the default), it is automatically set to the time zone used in time(x). This argument can be used to force using the local time zone or any other time zone instead of UTC as time zone.
dates	 numeric, factor, POSIXct or POSIXt object indicating how to obtain the dates and times for each column of x (e.g., gauging station). If dates is a number, it indicates the index of the column in x that stores the date and times. If dates is a factor, it is converted into POSIXct class, using the date format specified by date.fmt If dates is already of POSIXct or POSIXt class, this function verifies that the number of elements on it be equal to the number of elements in x.
date.fmt	character indicating the format in which the dates are stored in dates, By de- fault date.fmt=%Y-%m-%d %H:%M:%S. See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric"
out.type	 character indicating how should be returned the missing values for each temporal scale. Valid values are: -) percentage: the missing values are returned as an real value, representing the percentage of missing values in each temporal scale. -) amount: the missing values are returned as an integer value, representing the absolute amount of missing values in each temporal scale.
	further arguments passed to or from other methods.

Details

The amount of missing values in each temporal scale is computed just by counting the amount of NAs in each hour / day / week / month / quarter / season / year, while the percentage of missing values in each temporal scale is computed by dividing the previous number by the total number of data elements in each hour / day / week / month / quarter / season / year.

This function was developed to allow the selective removal of values when agregting from a high temporal resolution into a lower temporal resolution (e.g., from hourly to daily or from daily to monthly), using any of the temporal aggregation functions available int his package (e.g., hourly2daily, daily2monthly)

Value

a zoo object with the percentage/amount of missing values for each temporal scale selected by the user.

cmv

daily2weekly Daily-> Weekly

Description

Generic function for transforming a DAILY (or sub-daily) regular time series into a WEEKLY one

Usage

Arguments

x	zoo, data.frame or matrix object, with (sub)daily time series. Measurements at several gauging stations can be stored in a data.frame or matrix object, and in that case, each column of x represents the time series measured in each gauging station, and the column names of x have to correspond to the ID of each station (starting by a letter).
FUN	Function that have to be applied for transforming from daily to weekly time step (e.g., for precipitation FUN=sum and for temperature and streamflow ts FUN=mean).
	FUN MUST accept the na.rm argument, because na.rm is passed to FUN.
na.rm	Logical. Should missing values be removed? -) TRUE : the weekly values are computed only for weeks with a percentage of missing values less than na.rm.max -) FALSE: if there is AT LEAST one NA within a month, the corresponing weekly values in the output object will be NA.
na.rm.max	Numeric in [0, 1]. It is used to define the maximum percentage of missing values allowed in each month to keep the weekly aggregated value in the output object of this function. In other words, if the percentage of missing values in a given

	month is larger or equal than na.rm.max the corresponding weekly value will be NA.
dates	numeric, factor or Date object indicating how to obtain the dates for each gaug- ing station
	If dates is a number (default), it indicates the index of the column in x that stores the dates
	If dates is a factor, it is converted into Date class, using the date format speci- fied by date.fmt
	If dates is already of Date class, the code verifies that the number of days on it be equal to the number of elements in x
date.fmt	character indicating the format in which the dates are stored in <i>dates</i> , e.g. %Y-%m-%d. See format in as.Date.
	ONLY required when class(dates)=="factor" or class(dates)=="numeric".
out.type	Character that defines the desired type of output. Valid values are: -) data.frame: a data.frame, with as many columns as stations are included in x, and row names indicating the month and year for each value.
	-) db : a data.frame, with 4 columns will be produced.
	The first column (StationID) stores the ID of the station,
	The second column (Year) stores the year The third column (Month) stores the Month
	The fourth column (Value) stores the numerical values corresponding to the val- ues specified in the three previous columns.
out.fmt	OPTIONAL. Only used when x is a matrix or data.frame object /cr character, for selecting if the result will be a matrix/data.frame or a zoo object. Valid values are: numeric, zoo.
verbose	logical; if TRUE, progress messages are printed
	arguments additional to na.rm passed to FUN.

Value

a zoo object with weekly time frequency

```
dip
```

Days in Period

Description

Given any starting and ending dates, it generates:

1) a vector of class Date with all the days between from and to (both of them included), OR

2) the amount of days between the two dates

Usage

dip(from, to, date.fmt = "%Y-%m-%d", out.type = "seq")

Arguments

from	Character indicating the starting date for creating the sequence. It has to be in the format indicated by date.fmt.
to	Character indicating the ending date for creating the sequence. It has to be in the format indicated by date.fmt.
date.fmt	<pre>character indicating the format in which the dates are stored in from and to, e.g. %Y-%m-%d. See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric".</pre>
out.type	Character indicating the type of result that is given by this function. Valid values are: 1) seq : a vector of class Date with all the days between the two dates, OR 2) nmbr: a single numeric value with the amount of days between the two dates.

Value

Depending on the value of out.type, it returns:

1) a vector of class Date with all the days between from and to (both of them included), OR

2) the amount of days between the two dates

```

diy

Days in Year

Description

Given a single numeric value representing a year, it generates: 1) a vector of dates with all the days within the year, OR

2) the amount of days in the specified year

Usage

diy(year, out.type = "seq")

Arguments

year	numeric, the year for which the sequence of days will be generated
out.type	Character indicating the type of result that is given by this function. Valid values
	are:
	-) seq : a vectorial sequence with all the days within the given year
	-) nmbr: the number of days in the vectorial sequence with all the days within
	the given year

dm2seasonal

(sub)Daily/Monthly -> Seasonal Values

Description

Generic function for computing a seasonal value for every year of a sub-daily/daily/weekly/monthly time series

Usage

Arguments

X	zoo, xts, data.frame or matrix object, with sub-daily, daily, weekly or monthly time series.Measurements at several gauging stations can be stored in a data.frame of matrix object, and in that case, each column of x represent the time series measured in each gauging station, and the column names of x have to correspond to the ID of each station (starting by a letter).
season	character, indicating the weather season to be used for selecting the data. Valid values are:-) DJF : December, January, February-) MAM : March, April, May

36
	 -) JJA : June, July, August -) SON : September, October, November -) DJFM: December, January, February, March -) AM : April, May -) JJAS: June, July, August, September -) ON : October, November
FUN	Function that will be applied to ALL the values of x belonging to the given weather season (e.g., FUN can be some of mean, max, min, sd). The FUN value for the winter season (DJF or DJFM) is computed consid- ering the consecutive months of December, January and February/March . See 'Note' section.
na.rm	 Logical. Should missing values be removed? -) TRUE : the seasonal values are computed considering only those values different from NA (very important when FUN=sum) -) FALSE: if there is AT LEAST one NA within a weather season, the corresponding seasonal values are NA
out.fmt	 Character indicating the date format for the output time series. See format in as.Date. Possible values are: -) %Y : only the year will be used for the time. Default option. (e.g., "1961" "1962") -) %Y-%m-%d: a complete date format will be used for the time. (e.g., "1961-01-01" "1962-01-01")
dates	numeric, factor or Date object indicating how to obtain the dates. If dates is a number (default), it indicates the index of the column in x that stores the dates If dates is a factor, it is converted into Date class, by using the date format specified by date.fmt If dates is already of Date class, the code verifies that the number of days on it be equal to the number of elements in x
date.fmt	Character indicating the format in which the dates are stored in <i>dates</i> , e.g. %Y-%m-%d. See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric".
out.type	 Character that defines the desired type of output. Valid values are: -) data.frame: a data.frame, with as many columns as stations are included in x, the year corresponding to each seasonal value are used as row names. -) db : a data.frame, with 4 columns will be produced. The first column (StationID) stores the ID of the station The second column (Year) stores the year, The third column (Season) stores the season, The fourth column (Value) contains the seasonal value corresponding to the values specified in the previous three columns
	further arguments passed to or from other methods.

Value

A numeric vector with the seasonal values for all the years in which x is defined.

Warning

For any year, the FUN value for the winter season (DJF), is computed considering only January and February, and the value of December is used for computing the winter value of the next year.

Note

FUN is applied to all the values of x belonging to the selected season, so the results of this function depends on the frequency sampling of x and the type of function given by FUN

Author(s)

## Mean winter (DJF) values of streamflow for each year of 'x'
dm2seasonal(x, FUN=mean, season="DJF")
subdaily2seasonal(x, FUN=mean, season="DJF") # same as above
```

drawTimeAxis

Customized Time Axis

Description

For a nice time series plot, this function draws a customized time axis, with annual, monthly, daily and sub-daily time marks and labels.

drawTimeAxis

Usage

Arguments

x	time series that will be plotted using the X axis that will be draw class(x) must be ts or zoo
tick.tstep	Character indicating the time step that have to be used for putting the ticks on the time axis. Valid values are: auto, years, quarters, months, weeks, days, hours, minutes, seconds.
lab.tstep	Character indicating the time step that have to be used for putting the labels on the time axis. Valid values are: auto, years, quarters, months, weeks, days, hours, minutes, seconds.
lab.fmt	<pre>Character indicating the format to be used for the label of the axis. See format in as.Date. If not specified (lab.fmt=NULL), it will try to use: -) "%Y-%m-%d" when lab.tstep=="days", -) "%b-%Y" when lab.tstep=="year" or lab.tstep=="month".</pre>
cex.axis	magnification of axis annotation relative to cex (See par).
mgp	The margin line (in mex units) for the axis title, axis labels and axis line (See par). Default value is $mgp = c(3, 2, 0)$.
	further arguments passed to the axis function or from other methods.

Note

From version 0.3-0 it changed its name from drawxaxis to drawTimeAxis, in order to have a more intuitive name. The old drawxaxis function is deprecated, but still be kept for compatibility reasons.

Examples

```
## Loading the SanMartino precipitation data
data(SanMartinoPPts)
x <- window(SanMartinoPPts, end=as.Date("1930-12-31"))</pre>
```

```
## Plotting the daily ts only, and then automatic 'x' axis
plot(x, xaxt = "n", xlab="Time")
drawTimeAxis(x)
```

```
## Plotting the daily ts only, and then monthly ticks in the 'x' axis,
## with annual labels.
plot(x, xaxt = "n", xlab="Time")
drawTimeAxis(x, tick.tstep="months", lab.tstep="years")
```

dwdays

Description

Given a daily time series (usually precipitation), this function computes the average amount of wet/dry days in each month.

Usage

Arguments

x	zoo, data.frame or matrix object, usually with daily time series of precipitation. Measurements at several gauging stations can be stored in a data.frame of matrix object, and in that case, each column of x represent the time series measured in each gauging station, and the column names of x have to correspond to the ID of each station (starting by a letter).
thr	numeric. Value of daily precipitation used as threshold for classifying a day as dry/wet or not. Days with a precipitation value larger to thr are classified as <i>wet days</i> , whereas precipitation values lower to thr are classified as <i>dry days</i> .
type	character, indicating if the daily values have to be classified as dry or wet days. It works linked to the values specified in thr. Valid values are: wet, dry.
na.rm	Logical. Should missing values be removed before counting?
dates	numeric, factor or Date object indicating how to obtain the dates If dates is a number (default), it indicates the index of the column in x that stores the dates If dates is a factor, it is converted into Date class, using the date format specified by date.fmt If dates is already of Date class, the code verifies that the number of days in dates be equal to the number of element in x

date.fmt	character indicating the format in which the dates are stored in dates, e.g. %Y-%m-%d
	See format in as.Date.
	ONLY required when class(dates)=="factor" or class(dates)=="numeric".
verbose	logical; if TRUE, progress messages are printed
	further arguments passed to or from other methods.

Author(s)

Mauricio Zambrano-Bigiarini, <mzb.devel@gmail>

Examples

```
## Loading the SanMartino precipitation data
data(SanMartinoPPts)
x <- SanMartinoPPts
## Average amount of wet days in each month (for this example, this means days</pre>
```

with precipitation larger than 0.1mm)
dwdays(x, thr=0.1)

dwi

Days with Information

Description

This function generates a table indicating the number of days with information (<>NA) within a zoo object, aggregated by year, month or month per year.

Usage

```
dwi(x, ...)
## Default S3 method:
dwi(x, out.unit = "years", from = start(x), to = end(x),
    date.fmt = "%Y-%m-%d", tstep="days", ...)
## S3 method for class 'zoo'
dwi(x, out.unit = "years", from = start(x), to = end(x),
    date.fmt = "%Y-%m-%d", tstep="days", ...)
## S3 method for class 'data.frame'
dwi(x, out.unit = "years", from, to, date.fmt = "%Y-%m-%d", tstep="days",
    dates = 1, verbose = TRUE, ...)
## S3 method for class 'matrix'
dwi(x, out.unit = "years", from, to, date.fmt = "%Y-%m-%d", tstep="days",
    dates = 1, verbose = TRUE, ...)
```

Arguments

x	zoo, data.frame or matrix object, with daily/monthly/annual time series. Measurements at several gauging stations can be stored in a data.frame of matrix object, and in that case, each column of x represent the time series measured in each gauging station, and the column names of x have to correspond to the ID of each station (starting by a letter).
out.unit	<pre>aggregation time for the computation of the amount of days with information. Valid values are: -) months: monthly; -) years : annual; -) mpy : month per year (not available for data.frames)</pre>
from	Character indicating the starting date for the computations. It has to be in the format indicated by date.fmt. When x is a data.frame and this value is not provided, the date corresponding to the first row of x is used
to	Character indicating the ending date for the computations. It has to be in the format indicated by date.fmt. When x is a data.frame and this value is not provided, the date corresponding to the last row of x is used
date.fmt	character indicating the format in which the dates are stored in <i>dates</i> , e.g. %Y-%m-%d. See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric".
tstep	Time step used for storing the values in x. Valid values are: days, months, years. Since the version 0.3-0 of hydroTSM, this argument is not required any more, because it is not used any longer.
dates	numeric, factor or Date object indicating how to obtain the dates for each column of x If dates is a number, it indicates the index of the column in x that stores the dates If dates is a factor, it is converted into Date class, using the date format specified by date.fmt If dates is already of Date class, the code verifies that the number of days in dates be equal to the number of element in x
verbose	logical; if TRUE, progress messages are printed
	further arguments passed to or from other methods.

## Plotting the amount of months with information per year in each station
matrixplot(a, var.type="Days", main="Number of months with info per year")
```

End(Not run)

EbroPPtsMonthly Ebro Monthly Precipitation Time Series

Description

Time series of monthly precipitation on 331 stations of the Ebro River basin (NW Spain), for the period January/1961 to December/1963.

Usage

```
data(EbroPPtsMonthly)
```

Format

A data frame with 331 monthly time series, plus the first field storing the dates corresponding to each row.

Details

Monthly time series of precipitation on 331 stations of the Ebro River basin (Spain), where some data were in-filled by using the MOSS method and from daily time series used in the technical report "Estudio de Recursos de la Cuenca del Ebro".

Source

Downloaded from the web site of the Confederacion Hidrografica del Ebro (CHE) http://www. chebro.es/ (original link http://oph.chebro.es/DOCUMENTACION/PrecipitacionMensualRelleno/PrecipitacionMensua

These data are intended to be used for research purposes only, being distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY.

extract

Extract from Zoo

Description

Extracts from a zoo object all the values belonging to a given month, year or weather season.

Usage

extract(x, ...)
Default S3 method:
extract(x, trgt, ...)
S3 method for class 'zoo'
extract(x, trgt, ...)

Arguments

х	zoo object
trgt	 numeric or character indicating the elements to extract from x. Valid values are: 1) integer(s) from 1 to 12: trgt is considered as month(s) (1=JAN, 2=FEB,, 12=DEC), and all the values in x belonging to the month(s) specified by trgt will be extracted. 2) integer(s) > 12: trgt is considered as year(s), and all the values in x belonging to the year(s) specified by trgt will be extracted 3) character: trgt is considered as a weather season, and all the values in x belonging to the season specified by trgt will be extracted. Valid values are: -) DJF : December, January, February -) MAM : March, April, May -) JJA : June, July, August -) SON : September, October, November -) DJFM: December, January, February, March

44

-) AM : April, May
-) JJAS: June, July, August, September
-) ON : October, November
further arguments passed to or from other methods

Value

. . .

a zoo object with the extracted values.

## S3 method for class 'data.frame'
fdc(x, lQ.thr=0.7, hQ.thr=0.2, plot=TRUE, log="y",
     main= "Flow Duration Curve", xlab="% Time flow equalled or exceeded",
     ylab="Q, [m3/s]", ylim, yat=c(0.01, 0.1, 1), xat=c(0.01, 0.025, 0.05),
     col=palette("default")[1:ncol(x)], pch=1:ncol(x), lwd=rep(1, ncol(x)),
     lty=1:ncol(x), cex=0.4, cex.axis=1.2, cex.lab=1.2, leg.txt=NULL,
     leg.cex=1, leg.pos="topright", verbose=TRUE, thr.shw=TRUE, new=TRUE, ...)
## S3 method for class 'zoo'
fdc(x, lQ.thr=0.7, hQ.thr=0.2, plot=TRUE, log="y",
     main= "Flow Duration Curve", xlab="% Time flow equalled or exceeded",
     ylab="Q, [m3/s]", ylim, yat=c(0.01, 0.1, 1), xat=c(0.01, 0.025, 0.05),
     col=palette("default")[1:NCOL(x)], pch=1:NCOL(x), lwd=rep(1, NCOL(x)),
     lty=1:NCOL(x), cex=0.4, cex.axis=1.2, cex.lab=1.2, leg.txt=NULL,
     leg.cex=1, leg.pos="topright", verbose=TRUE, thr.shw=TRUE, new=TRUE, ...)
```

Arguments

x	numeric, zoo, data.frame or matrix object with the observed streamflows for which the flow duration curve have to be computed.
	Measurements at several gauging stations can be stored in a data.frame of matrix
	object, and in that case, each column of x represent the time series measured in
	each gauging station, and the column names of x have to correspond to the ID
	of each station (starting by a letter). When x is a matrix or data.frame, the flow
	duration curve is computed for each column.
lQ.thr	numeric, low-flow separation threshold. If this value is different from NA, a vertical line is drawn in this value, and all the values to the right of it should be
	deemed as low flows. Default value is 0.7.

46

hQ.thr	numeric, high-flow separation threshold. If this value is different from NA, a vertical line is drawn in this value, and all the values to the left of it should br deemed as high flows. Default value is 0.2.
plot	logical. Indicates if the flow duration curve should be plotted or not. Default value is TRUE.
log	character, indicates which axis has to be plotted with a logarithmic scale. Default value is y
main	See plot. An overall title for the plot: see title.
xlab	A title for the x axis. See plot.
ylab	A title for the y axis. See plot.
ylim	The y limits of the plot. See plot.default.
yat	Only used when log="y". numeric, with points at which tick-marks will try to be drawn in the Y axis, in addition to the defaults computed by R. See the at argument in Axis.
xat	Only used when log="x". numeric, with points at which tick-marks will try to be drawn in the x axis, in addition to the defaults computed by R. See the at argument in Axis.
col	The colors to be used for lines and points. Multiple colors can be specified so that each point can be given its own color. If there are fewer colors than points they are recycled in the standard fashion. Lines will all be plotted in the first colour specified. See plot.default.
pch	A vector of plotting characters or symbols: see points. See plot.default.
lwd	The line width, see par. See plot.default.
lty	The line type, see par. See plot.default.
cex	See plot.default. A numerical vector giving the amount by which plotting characters and symbols should be scaled relative to the default. This works as a multiple of par("cex"). 'NULL' and 'NA' are equivalent to '1.0'. Note that this does not affect annotation
cex.axis	magnification of axis annotation relative to 'cex'.
cex.lab	Magnification to be used for x and y labels relative to the current setting of 'cex'. See '?par'.
leg.txt	vector with the names that have to be used for each column of x.
leg.cex	numeric, indicating the character expansion factor for the legend, *relative* to current par("cex"). Default value = 1
leg.pos	keyword to be used to position the legend. One of the list "bottomright", "bot- tom", "bottomleft", "left", "topleft", "top", "topright", "right", "center". This places the legend on the inside of the plot frame at the given location. See legend.
verbose	logical; if TRUE, progress messages are printed (when x is a matrix or data.frame).
thr.shw	logical, indicating if the streamflow values corresponding to the user-defined thresholds 1Q. thr and hQ. thr have to be shown in the plot.
new	logical, if TRUE (default), a new plotting window is created.
•••	further arguments passed to or from other methods (to the plotting functions)

Value

numeric, matrix or data.frame whose columns contains the % of time each one of the streamflow magnitudes given as input was equalled or exceeded. The resulting values have to be multiplied by 100 to get a percentage.

When plot is TRUE (default), the resulting flow duration curve is plotted in a new window.

data(OcaEnOnaQts)

```
## Daily Flow Duration Curve
fdc(OcaEnOnaQts)
```

```
# Getting the streamflow values corresponding to 5 and 95% of time equalled or
# exceeded (and also the first streamflow value in 'x' just for verification)
x <- OcaEnOnaQts
# First streamflow value (x1=42.1 m3/s)
x1 <- x[1]
# Daily FDC for 'x'
y <- fdc(x)
# value of the FDC for x1 (y1=0.002739726)
y1 <- y[1]
# Performing cubic (or Hermite) spline interpolation of 'x' and 'y'
```

fdcu

fdcu

Flow Duration Curve with uncertainty bounds.

Description

Computes and plots the Flow Duration Curve (FDC) for the streamflows given by x and for two uncertainty bounds, with the possibility of plotting an additional FDC representing simulated streamflows for x, in order to compare them.

Usage

```
fdcu(x, lband, uband, ...)
## Default S3 method:
fdcu(x, lband, uband, sim=NULL, lQ.thr=0.7, hQ.thr=0.2, plot=TRUE, log="y",

     leg.txt=c("OBS", colnames(x), "95PPU"), leg.cex=1, leg.pos="auto",
     verbose= TRUE, thr.shw=TRUE, border=rep(NA, ncol(x)),
     bands.col=rep("lightcyan", ncol(x)), bands.density=rep(NULL, ncol(x)),
     bands.angle=rep(45, ncol(x)), new=TRUE, ...)
```

Arguments

x	 numeric, zoo, data.frame or matrix object with the observed streamflows for which the flow duration curve have to be computed. Measurements at several gauging stations can be stored in a data.frame of matrix object, and in that case, each column of x represent the time series measured in each gauging station, and the column names of x have to correspond to the ID of each station (starting by a letter). When x is a matrix or data.frame, the flow duration curve is computed for each column.
lband	numeric, zoo, data.frame or matrix object with the streamflows representing the the lower uncertainty bound of x, for which the flow duration curve have to be computed.Measurements at several gauging stations can be stored in a data.frame of matrix object. When 1band is a matrix or data.frame, the flow duration curve is
	computed for each column.
uband	numeric, zoo, data.frame or matrix object with the streamflows representing the the upper uncertainty bound of x, for which the flow duration curve have to be computed.
	Measurements at several gauging stations can be stored in a data.frame of ma- trix object. When uband is a matrix or data.frame, the flow duration curve is computed for each column.
sim	OPTIONAL.numeric, zoo, data.frame or matrix object with the streamflows simulated for x, for which the flow duration curve have to be computed.Measurements at several gauging stations can be stored in a data.frame of matrix object. When sim is a matrix or data.frame, the flow duration curve is computed for each column.

lQ.thr	numeric, low flows separation threshold. If this value is different from 'NA', a vertical line is drawn in this value, and all the values to the left of it are deemed low flows.
hQ.thr	numeric, high flows separation threshold. If this value is different from 'NA', a vertical line is drawn in this value, and all the values to the right of it are deemed high flows
plot	logical. Indicates if the flow duration curve should be plotted or not.
log	character, indicates which axis has to be plotted with a logarithmic scale. Default value is y.
main	See plot. An overall title for the plot: see title.
xlab	See plot. A title for the x axis: see title.
ylab	See plot. A title for the y axis: see title.
ylim	See plot.default. The y limits of the plot.
yat	Only used when log="y". numeric, with points at which tick-marks will try to be drawn in the Y axis, in addition to the defaults computed by R. See the at argument in Axis.
xat	Only used when $\log = x^{n}$. numeric, with points at which tick-marks will try to be drawn in the x axis, in addition to the defaults computed by R. See the at argument in Axis.
col	See plot.default. The colors for lines and points. Multiple colors can be specified so that each point can be given its own color. If there are fewer colors than points they are recycled in the standard fashion. Lines will all be plotted in the first colour specified.
pch	See plot.default. A vector of plotting characters or symbols: see points.
lwd	See plot.default. The line width, see par.
lty	See plot.default. The line type, see par.
cex	See plot.default. A numerical vector giving the amount by which plotting characters and symbols should be scaled relative to the default. This works as a multiple of par("cex"). 'NULL' and 'NA' are equivalent to '1.0'. Note that this does not affect annotation.
cex.axis	magnification of axis annotation relative to 'cex'.
cex.lab	Magnification to be used for x and y labels relative to the current setting of 'cex'. See '?par'.
leg.txt	vector with the names that have to be used for each column of x.
leg.cex	numeric, indicating the character expansion factor for the legend, *relative* to current par("cex"). Default value = 1
leg.pos	 keyword to be used to position the legend. One of the list '"bottomright", "bottom", "bottomleft", "left", "topleft", "top", "topright", "right", "center". This places the legend on the inside of the plot frame at the given location. See legend. When leg.pos="auto", the legend provided by leg.txt is located on the 'bottomleft' when log="y" and on the 'topright' otherwise

verbose	logical; if TRUE, progress messages are printed
thr.shw	logical, indicating if the streamflow values corresponding to the user-defined thresholds lQ. thr and hQ. thr have to be shown in the plot. When leg.pos="auto", the legend with the threshold values is located on the 'topright' when log="y" and on the 'bottomleft' otherwise
border	See polygon. The color to draw the border of the polygon with the uncertainty bounds. The default, 'NA', means to omit borders.
bands.col	See polygon. The color for filling the polygon. The default, 'NA', is to leave polygons unfilled, unless bands.density is specified. If bands.density is specified with a positive value this gives the color of the shading lines.
bands.density	See polygon. The density of shading lines for the polygon with the uncertainty bounds, in lines per inch. The default value of 'NULL' means that no shading lines are drawn. A zero value of bands.density means no shading nor filling whereas negative values (and 'NA') suppress shading (and so allow color filling).
bands.angle	See polygon. The slope of shading lines for the polygon with the uncertainty bounds, given as an angle in degrees (counter-clockwise).
new	logical, if TRUE, a new plotting window is created.
	further arguments passed to or from other methods (to the plotting functions)

Note

If you do not want to use logarithmic scale for the streamflow axis, you can do it by passing the log=" " to the ... argument.

Plotting the flow duration curve corresponding to 'q', with two uncertainty bounds fdcu(q, lband, uband)

hip

Hours in Period

Description

Given any starting and ending date/time objects, it generates:

1) a vector of class c("POSIXct" "POSIXt") with all the hours between the two date/time objects (both of them included), OR

2) the amount of hours between the two date/time objects

Usage

hip(from, to, date.fmt="%Y-%m-%d %H", out.type = "seq", tz="UTC")

Arguments

from	Character or POSIXct object indicating the starting date/time for creating the sequence. It has to be in the format indicated by date.fmt.
to	Character indicating the ending date/time for creating the sequence. It has to be in the format indicated by date.fmt.
date.fmt	character indicating the format in which the date/time objects are stored in from and to, e.g. %Y-%m-%d %H:%M. See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric".
out.type	 Character indicating the type of result that is given by this function. Valid values are: 1) seq : a vector of class Date with all the days between the two dates, OR 2) nmbr: a single numeric value with the amount of days between the two dates.
tz	specification of the desired time zone yo be used. System-specific (see time zones), but "" is the current time zone, and "GMT" (the default value) is UTC (Universal Time, Coordinated). See Sys.timezone and as.POSIXct. This argument can be used when working with subdaily zoo objects to force using the local time zone instead of GMT as time zone.

Value

Depending on the value of out.type, it returns: 1) a vector of class c("POSIXct" "POSIXt") with all the hours between from and to (both of them included), OR

2) the amount of hours between the two date/time objects

## starting and ending date/time objects with hours and skipping the minutes (default)
hip("1961-01-01 00", "1961-12-31 00")
```

Sequence of hours between "1961-01-01 00:00" and "1961-01-10 00:00", giving the ## starting and ending date/time objects only with hours and minutes(skipping the minutes) hip("1961-01-01 00:00", "1961-12-31 00:00", date.fmt="%Y-%m-%d %H:%M")

Number of hours between the 10:00 AM of "1961-Jan-02" and the 11:00 AM of "1961-Jan-01",
using "%d/%m/%Y" as date/time format.
hip("01/01/1961 10", "02/01/1961 11", date.fmt= "%d/%m/%Y %H", out.type = "nmbr")

hydropairs

Visual Correlation Matrix

Description

Visualization of a correlation matrix. On top the (absolute) value of the correlation plus the result of the cor.test as stars. On bottom, the bivariate scatterplots, with a fitted line. On the diagonal, an histogram of each variable.

Usage

```
hydropairs(x, dec = 3, use = "pairwise.complete.obs", method = "pearson",...)
```

Arguments

х	data.frame or matrix object with measurements at several locations. Each col-
	umn of x represent values measured at different locations.
dec	decimal places to be used for showing the correlation values

54

hydropairs

use	See cor. An optional character string giving a method for computing covari- ances in the presence of missing values. This must be (an abbreviation of) one of the strings "everything", "all.obs", "complete.obs", "na.or.complete", or "pair- wise.complete.obs".
method	See cor. A character string indicating which correlation coefficient (or covari- ance) is to be computed. One of "pearson" (default), "kendall", or "spearman", can be abbreviated
	further arguments passed to or from other methods, in particular it is used in the pairs function.

Value

On top	the (absolute) value of the correlation plus the result of the cor.test as points
On bottom	the bivariate scatterplots, with a fitted line
On diagonal	histograms (from pairs)

Note

Original idea taken from the R Graph Gallery (nowadays not available on its original link: http://addictedtor.free.fr/graphiques

Histogram panel was taken from the R help of the original pairs function

          win.len1=0, win.len2=0, tick.tstep="auto", lab.tstep="auto"
          lab.fmt=NULL, cex=0.3, cex.main=1.3, cex.lab=1.3, cex.axis=1.3,
          col=c("blue", "lightblue", "lightblue"),
          from=NULL, to=NULL, dates=1, date.fmt= "%Y-%m-%d",
       stype="default", season.names=c("Winter", "Spring", "Summer", "Autumn"),
          h=NULL, ...)
```

hydroplot

Default S3 method: sname2plot(x, sname, FUN, na.rm=TRUE, ptype="ts+boxplot+hist", pfreq="dma", var.type, var.unit="units", main=NULL, xlab="Time", ylab=NULL, win.len1=0, win.len2=0, tick.tstep="auto", lab.tstep="auto", lab.fmt=NULL, cex=0.3, cex.main=1.3, cex.lab=1.3, cex.axis=1.3, col=c("blue", "lightblue", "lightblue"), dates=1, date.fmt = "%Y-%m-%d", from=NULL, to=NULL, stype="default", season.names=c("Winter", "Spring", "Summer", "Autumn"), h=NULL, ...) ## S3 method for class 'zoo' sname2plot(x, sname, FUN, na.rm=TRUE, ptype="ts+boxplot+hist", pfreq="dma", var.type, var.unit="units", main=NULL, xlab="Time", ylab=NULL, win.len1=0, win.len2=0, tick.tstep="auto", lab.tstep="auto", lab.fmt=NULL, cex=0.3, cex.main=1.3, cex.lab=1.3, cex.axis=1.3, col=c("blue", "lightblue", "lightblue"), dates=1, date.fmt = "%Y-%m-%d", from=NULL, to=NULL, stype="default", season.names=c("Winter", "Spring", "Summer", "Autumn"), h=NULL, ...) ## S3 method for class 'data.frame' sname2plot(x, sname, FUN, na.rm=TRUE, ptype="ts+boxplot+hist", pfreq="dma", var.type, var.unit="units", main=NULL, xlab="Time", ylab=NULL, win.len1=0, win.len2=0, tick.tstep="auto", lab.tstep="auto", lab.fmt=NULL, cex=0.3, cex.main=1.3, cex.lab=1.3, cex.axis=1.3, col=c("blue", "lightblue", "lightblue"), dates=1, date.fmt = "%Y-%m-%d", from=NULL, to=NULL, stype="default", season.names=c("Winter", "Spring", "Summer", "Autumn"), h=NULL, ...)

Arguments

X	zoo, xts or data.frame object, with columns storing the time series of one or more gauging stations.
sname	ONLY required when x is a data frame. Character representing the name of a station, which have to correspond to one column name in x
FUN	ONLY required when var.type is missing AND pfreq != "o". Function that have to be applied for transforming from daily to monthly or an- nual time step (e.g., For precipitation FUN=sum and for temperature and flow ts, FUN=mean)
na.rm	Logical. Should missing values be removed before the computations?
ptype	 Character indicating the type of plot that will be plotted. Valid values are: -) ts => only time series -) ts+boxplot => only time series + boxplot

	 -) ts+hist => only time series + histogram -) ts+boxplot+hist => time series + boxplot + histogram
pfreq	Character indicating how many plots are desired by the user. Valid values are: -) dma : Daily, Monthly and Annual values are plotted -) dm : Daily and Monthly values are plotted
) data is builty tailed into the protect -) ma : Monthly and Annual values are plotted -) o : Only the original zoo object is plotted, and ptype is changed to ts -) seasonal: Line and bloxplots of seasonal time series (see stype and season.names). When pfreq is seasonal, ptype is set to ts+boxplot
var.type	ONLY required when FUN is missing. character representing the type of variable being plotted. Used for determining the function used for computing the monthly and annual values when FUN is missing. Valid values are: -) Precipitation => FUN=sum -) Temperature => FUN=mean -) Flow => FUN=mean
var.unit	Character representing the measurement unit of the variable being plotted. ONLY used for labelling the axes (e.g., "mm" for precipitation, "C" for temperature, and "m3/s" for flow.)
main	Character representing the main title of the plot. If the user do not provide a title, this is created automatically as: main=paste(var.type, "at", sname, sep=""),
xlab	A title for the x axis. See plot.
ylab	A title for the y axis. See plot.
win.len1	number of days for being used in the computation of the first moving average. A value equal to zero indicates that this moving average is not going to be com- puted.
win.len2	number of days for being used in the computation of the second moving aver- age. A value equal to zero indicates that this moving average is not going to be computed.
tick.tstep	Character indicating the time step that have to be used for putting the ticks on the time axis. Valid values are: -) days, -) months,
lab.tstep	 -) years Character indicating the time step that have to be used for putting the labels on the time axis. Valid values are: -) days, -) months, -) years
lab.fmt	Character indicating with the format to be used for the label of the axis. See format in as.Date. If not specified, it will try "%Y-%m-%d" when lab.tstep=="days", "%b" when lab.tstep=="month", and "%Y" when lab.tstep=="year".
cex	A numerical value giving the amount by which plotting text and symbols should be magnified relative to the default. (See par).

hydroplot

cex.main	The magnification to be used for main titles relative to the current setting of cex (See par).
cex.lab	The magnification to be used for x and y labels relative to the current setting of cex (See par).
cex.axis	The magnification to be used for axis annotation relative to the current setting of cex (See par).
col	A character vector with 3 elements, representing the colors to be used for plot- ting the lines of the ts, the boxplots, and the histograms, respectively. When pfreq="o", only one character element is needed. See plot.default).
dates	ONLY required when x is a data frame. It is a numeric, factor or Date object indicating how to obtain the dates corresponding to the sname station. If dates is a number (default), it indicates the index of the column in x that stores the dates If dates is a factor, it is converted into Date class, using the date format specified by date.fmt If dates is already of Date class, the code verifies that the number of days in dates be equal to the number of element in x
date.fmt	Character indicating the format in which the dates are stored in <i>dates</i> , <i>from</i> and <i>to</i> . See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric".
from	OPTIONAL, used for extracting a subset of values. Character indicating the starting date for the values to be extracted. It must be provided in the format specified by date.fmt.
to	OPTIONAL, used for extracting a subset of values. Character indicating the ending date for the values to be extracted. It must be provided in the format specified by date.fmt.
stype	 OPTIONAL, only used when pfreq=seasonal. character, indicating which weather seasons will be used for computing the output. Possible values are: -) default => "winter"= DJF = Dec, Jan, Feb; "spring"= MAM = Mar, Apr, May; "summer"= JJA = Jun, Jul, Aug; "autumn"= SON = Sep, Oct, Nov -) FrenchPolynesia => "winter"= DJFM = Dec, Jan, Feb, Mar; "spring"= AM = Apr, May; "summer"= JJAS = Jun, Jul, Aug, Sep; "autumn"= ON = Oct, Nov
season.names	OPTIONAL, only used when pfreq=seasonal. character of length 4 indicating the names of each one of the weather seasons defined by stype.These names are only used for plotting purposes
h	OPTIONAL, only used when pfreq=seasonal, for plotting horizontal lines in each seasonal plot. numeric, with 1 or 4 elements, with the value used for plotting an horizontal line in each seasonal plot, in the following order: winter (DJF), spring (MAM), summer (JJA), autumn (SON).
	further arguments passed to the plot.zoo and axis functions or from other methods.

Details

Plots of the daily/monthly/annual/seasonal values of the time series given as input. Depending on the value of pfreq, daily, monthly, annual and/or seasonal time series plots, boxplots and histograms are produced.

Depending on the value of ptype, time series plots, boxplots and/or histograms are produced.

infillxy

```
stype="default")
```

infillxy

Infills NA values

Description

Infill all the missing values (NA) in x with the corresponding values in sim.

Usage

```
infillxy(x, ...)
## Default S3 method:
infillxy(x, sim, ...)
## S3 method for class 'matrix'
infillxy(x, sim, ...)
## S3 method for class 'data.frame'
infillxy(x, sim, ...)
```

Arguments

Х	numeric, data.frame or matrix in which some values are missing (NA).
sim	numeric, data.frame or matrix, with the same dimension of x, which contains the values that will be used for infilling the missing (NA) values in x
	further arguments passed to or from other methods.

Details

It gives as a result an object of the same dimension of x, in which all the NA values were infilled with the corresponding values of sim.

Author(s)

Mauricio Zambrano-Bigiarini, <mzb.devel@gmail>

Examples

obs <- c(1, NA, 3, 4, NA, 5) sim <- rep(2, 6)

Filling in the missing values in 'x' with the corresponding values in 'sim'
infillxy(x=obs, sim)

istdx

Description

This function back transforms a standarized vector/matrix z into their original values, i.e., re-scales all the values in the [0,1] interval to the original range of values z = re-scale(x) = x*[xmax - xmin] + xmin.

Usage

```
istdx(x, ...)
## Default S3 method:
istdx(x, xmin, xrange, ...)
```

Arguments

x	standarized vector or matrix to be re-scaled, all the values have to be in the range [0,1]
xmin	 numeric with the minimum value(s) in the original x -) if x is a vector, xmin has to be a real -) if x is a matrix/data.frame, xmin has to be a vector, with the minimum values for each column of the original x. In this case, the vector of minimums can be obtained as: xmin <- apply(x, 2, min, na.rm=TRUE)
xrange	 numeric with the range of value(s) in the original x -) if x is a vector, xrange has to be a real -) if x is a matrix/data.frame, xrange has to be a vector, with the range of values for each column of the original x. In this case, the vector of ranges can be obtained as: xrange <- apply(x, 2, range, na.rm=TRUE) xrange <- apply(xrange, 2, diff, na.rm=TRUE)
	further arguments passed to or from other methods

izoo2rzoo

Irregular Zoo -> Regular Zoo

Description

It takes an irregular zoo object (with non-existing values for some dates) and converts it into a regularly spaced zoo object within the time period defined by from and to, by filling the missing dates with 'NA'

Usage

Arguments

x	irregular zoo object (vector or matrix) representing a time series (very likely read with some user-defined procedure, and with some missing values for particular days/months/years)
from	Character indicating the starting date for creating the regularly spaced zoo object. The default value corresponds to the date of the first element of x It has to be in the format indicated by date.fmt.
to	Character indicating the ending date for creating the regularly spaced zoo object. The default value corresponds to the date of the last element of x It has to be in the format indicated by date.fmt.
date.fmt	character indicating the format in which the dates are stored in from and to, e.g. %Y-%m-%d. See 'Details' section in strptime. By default, date.fmt is missing, and it is automatically set to %Y-%m-%d when time(x) is Date object, and set to %Y-%m-%d %H:%M:%S when x is a sub-daily zoo object.
tstep	character, indicating the time step used for creating the time sequence going from from to to that will be used as time(x) Valid values are (but not limited to) hours, days, months, years. By default, tstep is missing, and it is automatically set to "minutes" when sfreq(x) is min, to "hours" when sfreq(x) is hourly, to "days" when sfreq(x) is daily, to "weeks" when sfreq(x) is weekly, to "months" when sfreq(x) is monthly, to "quarters" when sfreq(x) is quarterly, and to "years" when sfreq(x) is annual.
tz	character, with the specification of the time zone used for from, to. System- specific (see time zones), but "" is the current time zone, and "GMT" is UTC (Universal Time, Coordinated). See Sys.timezone and as.POSIXct.
	If tz is missing (the default), it is automatically set to the time zone used in time(x).
	This argument can be used when working with sub-daily zoo objects to force using time zones other than the local time zone for from and to. It should be used with caution, being well aware of the time zone of the data. See examples.
	further arguments passed to or from other methods

Details

If the full time period of x is a subset of the time period defined by from and to, the time period of the resulting zoo is the one defined by from and to, assigning 'NA' to all the dates in which x do not have a value.

izoo2rzoo

Value

a regularly spaced zoo object, with values given by x and time stamps going from from to to at intervals defined by tsteps

Author(s)

Mauricio Zambrano-Bigiarini, <mzb.devel@gmail>

Examples

```
##
## Example 1: Adding NA for February 29th to an existing zoo object
# dummy values and dates (February 29th is not present !)
x <- 1:9
dates <- c("1964-02-25", "1964-02-26", "1964-02-27", "1964-02-28", "1964-03-01",
           "1964-03-02", "1964-03-03", "1964-03-04", "1964-03-05")
# From 'character' to 'Date' class
dates <- as.Date(dates)</pre>
## From 'numeric' to 'zoo' class
( x <- zoo(x, dates) ) # Feb 29th is still not present in 'x'
## checking the length of 'x'
length(x) # 9 elements (there is no data for Feb 29th)
## Adding a missing value (NA in this case) for Feb 29th
(y \le izoo2rzoo(x))
## checking the new length
length(y) # 1 element more than the original 'x' (thre is an NA value in Feb 29th)
##
## Example 2: Extending the original 'x' object from February 1st to the end of March,
#
             assigning 'NA' to the days in which 'x' do not have a value.
( y <- izoo2rzoo(x, from="1964-02-01", to="1964-03-31") )
##
## Example 3: Working with a zoo matrix with two identical 'x' time series,
             from 1964-02-25 to 1964-03-05
##
(Y \leq cbind(x,x))
```

Adding a missing value (NA in this case) for Feb 29th in all the columns of Y (rY <- izoo2rzoo(Y))

```
##
## Example 4: Working with hourly data, from 01:00 to 10:00 UTC on 12th December 2000
dates <- ISOdatetime(year=2000, month=12, day=12, hour=1:10, min=0, sec=0, tz="UTC")
values <- 1:10
      <- zoo(values, dates)
х
# removing four values in 'x', from 02:00 to 05:00, i.e., they will not be present
# anymore in 'x' at all, not even NA !)
x <- x[-c(2:5)]
time(x)
length(x)
# Adding missing values (NA in this case) from 02:00 to 05:00
y <- izoo2rzoo(x)</pre>
time(y)
length(y)
##
## Example 5: Extending hourly data to a DateTime before 'start(x)',
##
             specifying only the date.
##
             Time of 'x' is in local time zone (tz="") instead of UTC
dt <- hip("2021-01-01 00:00:00", "2021-01-01 20:00:00", tz="")
x <- zoo(0:20, dt)
(y <- izoo2rzoo(x, from="2020-12-31") )# 00:00:00 is ommited
##
## Example 6: Extending hourly data to a DateTime before 'start(x)',
##
             specifying date and time.
##
             Time of 'x' is in local time zone (tz="") instead of UTC
dt <- hip("2021-01-01 00:00:00", "2021-01-01 20:00:00", tz="")
x <- zoo(0:20, dt)
( y <- izoo2rzoo(x, from="2020-12-31 20:00:00") )
##
## Example 7: Extending hourly data to a DateTime after 'end(x)',
##
              specifying date and time.
##
              Time of 'x' is in local time zone (tz="") instead of UTC
dt <- hip("2021-01-01 00:00:00", "2021-01-01 20:00:00", tz="")
x <- zoo(0:20, dt)
( y <- izoo2rzoo(x, to="2021-01-02 12:00:00") )
##
## Example 8: Extending hourly data to a DateTime before 'start(x)'.
             Note that the 'tz' argument can be ommited in the 'hip' function,
##
##
             because by default it assumes UTC as time zone
dt <- hip("2021-01-01 00:00:00", "2021-01-01 20:00:00", tz="UTC")
x <- zoo(0:20, dt)
```

```
( y <- izoo2rzoo(x, from="2020-12-31 20:00:00", tz="UTC") )
```

```
##
## Example 9: Extending hourly data to a date before 'start(x)'. However, hourly 'x'
## values are given at HH:15:00 hours instead of HH:00:00 hours.
## Loading the time series of hourly streamflows for the station Karamea at Gorge
## Time Zone for 'KarameaAtGorgeQts' data is GMT+12 (see ?KarameaAtGorgeQts)
data(KarameaAtGorgeQts)
x <- KarameaAtGorgeQts
# Subsetting 'x' to its first day only
# (01/Jan/1980 08:15:00 - 01/Jan/1980 23:15:00)
x <- window(x, end="1980-01-01 23:59:00")
# Adding NA hourly data since 1979-12-31 21:15:00
izoo2rzoo(x, from="1979-12-31 21:15:00", tz="GMT+12")</pre>
```

KarameaAtGorgeQts Karamea at Gorge, time series of hourly streamflows

Description

Time series with hourly streamflows for the Karamea River(New Zealand) measured at the gauging station "Gorge", for the period 01/Jan/1980 to 31/Dec/1985. Station Number: 95102, Easting Coordinate (NZMG): 2444629.0, Northing Coordinate (NZMG): 5994427.0, Catchment Area (km2): 1160.0.

In November 25th, 2023, the time zone of this data sete was changed from "none" (i.e., your local time zone was used every time you loaded this dataset) to GMT+12, in order to avoid missing datetimes at times where daylight saving time ocurred. After this change, the initial DateTime of this dataset changed from "1980-01-01 08:15:00 -03" (in my local computer) to "1980-01-01 00:15:00" (everywhere). Only two NA elements were removed from the origanl dataset: the first one and the last one.

Usage

```
data(KarameaAtGorgeQts)
```

Format

zoo object.

ma

Description

Generic function for computing a moving (sliding) average of ts.

Usage

```
ma(x, ...)
## Default S3 method:
ma(x, win.len, FUN = mean, ...)
## S3 method for class 'zoo'
ma(x, win.len, FUN = mean, ...)
```

Arguments

Х	ts or zoo object.
win.len	number of terms that will be considered in the mean. It have to be odd
FUN	Function that have to be applied for computing the moving average. Usually, FUN MUST be mean
	further arguments passed to or from other methods.

Value

a vector with the moving average terms. The length of the resulting vector is the same of x, but the first and last (win.len-1)/2 elements will be NA.

Author(s)

Mauricio Zambrano-Bigiarini, <mzb.devel@gmail>

Examples

```
## Loading daily streamflows at the station Oca en Ona (Ebro River basin, Spain) ##
data(OcaEnOnaQts)
x <- OcaEnOnaQts
## Daily to Monthly ts
m <- daily2monthly(x, FUN=mean, na.rm=FALSE)
# Plotting the monthly values
plot(m, xlab="Time")
## Plotting the annual moving average in station 'x'
lines(ma(m, win.len=12), col="blue")</pre>
```

Description

Daily time series of precipitation, maximum and minimun air temperature at station Maquehue Temuco Ad. (DMC_ID:380013), Araucania Region, Chile (Lat:-38.770, Lon:-72.637), with data from 01/Jan/1950 to 31/Dec/2015 (including some gaps).

Usage

data(MaquehueTemuco)

Format

zoo matrix with 3 columns:

- -) pcp: daily precipitation, [mm/day].
- -) tmx: daily maximum air temperature, [degree Celsius].
- -) tmn: daily minimum air temperature, [degree Celsius].

Source

Provided by Center for Climate and Resilience Research, Universidad de Chile, Santiago, Chile (https://www.cr2.cl/bases-de-datos/, last accessed [Jan 2024]).

matrixplot

Matrixplot

Description

Plots a color matrix, representing the values stored in x.

Originally, it was thought to represent the amount of days with information per year in a set of gauging stations, but it can be used for plotting the information stored in any two dimensional matrix.

Usage

```
matrixplot(x, ColorRamp="Days", ncolors = 70, main = "", ...)
```

Arguments

Х	matrix to be plotted. Originally:
	-) Each column of x represent a different gauging station, and it stores the values
	measured on it
	-) Each row of x represent the years, and they stores the amount of days with
	information in each station
ColorRamp	Character or function defining a personalized color ramp for plotting the maps. Valid character values are in c("Days", "Precipitation", "Temperature", "PCPAnomaly", "PCPAnomaly2" "TEMPAnomaly", "TEMPAnomaly2", "TEMPAnomaly3").
ncolors	numeric, indicating the number of color intervals that will be used for represent- ing the information content of x.
main	Main title for the plot
	further arguments passed to levelplot function (lattice package) or from other methods

Examples

Description

Given any starting and ending dates, it generates:

a vector of class 'Date' with all the months between the two dates (both of them included), OR
 the amount of months between the two dates

Usage

mip(from, to, date.fmt = "%Y-%m-%d", out.type = "seq")

Arguments

from	Character indicating the starting date for creating the sequence. It has to be in the format indicated by date.fmt.
to	Character indicating the ending date for creating the sequence. It has to be in the format indicated by date.fmt.
date.fmt	Character indicating the format in which the dates are stored in from and to, e.g. %Y-%m-%d. See format in as.Date.
out.type	 character indicating the type of result that is given by this function. Valid values are: -) seq : a vectorial sequence with all the months within the given year -) nmbr: the number of days in the vectorial sequence with all the months within the given year

Value

Depending on the value of out.type, it returns:

1) a vector of class Date with all the months between from and to (both of them included), OR

2) a single numeric value with the amount of months between the two dates.

```

monthlyfunction Monthly Function

Description

Generic function for obtaining 12 monthly values of a zoo object, by applying any R function to ALL the values in the object belonging to each one of the 12 calendar months (Jan...Dec).

Usage

Arguments

x	zoo, xts, data.frame or matrix object, with daily or monthly time series. Measurements at several gauging stations can be stored in a data.frame of matrix object, and in that case, each column of x represent the time series measured in each gauging station, and the column names of x have to correspond to the ID of each station (starting by a letter).
FUN	Function that will be applied to ALL the values in x belonging to each one of the 12 months of the year (e.g., FUN can be some of mean, sum, max, min, sd).
na.rm	Logical. Should missing values be removed? -) TRUE : the monthly values and FUN are computed considering only those values in x different from NA -) FALSE: if there is AT LEAST one NA within a month, the corresponding monthly value will be NA

72
dates	It is only used when x is not a zoo object. numeric, factor, Date indicating how to obtain the dates. If dates is a number (default), it indicates the index of the column in x that stores the dates If dates is a factor, it is converted into 'Date' class, using the date format spec- ified by date. fmt If dates is already of Date class, the code verifies that the number of days in dates be equal to the number of elements in x
date.fmt	It is only used when x is not a zoo object. character indicating the format in which the dates are stored in <i>dates</i> , e.g. %Y-%m-%d. See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric".
out.type	It is only used when x is a matrix or data.frame. Character defining the desired type of output. Valid values are: -) data.frame: a data.frame, with 12 columns representing the months, and as many rows as gauging stations are included in x -) db : a data.frame, with 4 columns will be produced. Useful for a posterior boxplot The first column ('StationID') will store the ID of the station, The second column ('Year') will store the year, The third column ('Month') will store month, The fourth column ('Value') will contain the monthly value corresponding to the three previous columns.
verbose	Logical; if TRUE, progress messages are printed
	further arguments passed to or from other methods

Value

When x is a zoo object, a numeric vector with 12 elements representing the computed monthly value for each month.

When x is a data.frame which columns represent measurements at different gauging stations, the resulting object is a data.frame with 12 columns and as many rows as gauging stations are in x, each row storing the computed 12 monthly value for each gauging station.

Note

Due to the fact that FUN is applied over all the elements in x belonging to a given calendar month, its result will depend on the sampling frequency of x and the type of function provided by FUN (**special attention have to be put when** FUN=sum)

Examples

```
## Loading daily streamflows (3 years) at the station
## Oca en Ona (Ebro River basin, Spain)
data(OcaEnOnaQts)
x <- OcaEnOnaQts
## Mean monthly streamflows at station 'x'
monthlyfunction(x, FUN=mean, na.rm=TRUE)
*****
## Boxplot of monthly values
## Daily to Monthly
m <- daily2monthly(x, FUN=mean, na.rm=TRUE)</pre>
## Median of the monthly values at the station
monthlyfunction(m, FUN=median, na.rm=TRUE)
## Vector with the three-letter abbreviations of the month names
cmonth <- format(time(m), "%b")</pre>
## Creating ordered monthly factors
months <- factor(cmonth, levels=unique(cmonth), ordered=TRUE)</pre>
## Boxplot of the monthly values
boxplot( coredata(m) ~ months, col="lightblue", main="Monthly streamflows, [m3/s]")
## Loading the monthly time series of precipitation within the Ebro River basin.
data(EbroPPtsMonthly)
x <- EbroPPtsMonthly</pre>
## Dates of 'x'
dates <- as.Date(x[,1])</pre>
## Monthly precipitation of all the stations in 'x'
## Not run:
## Sum of the monthly values in each station of 'x'
z <- zoo( x[, 2:ncol(x)], dates)</pre>
# Amount of years in 'x' (needed for computing the average)
nyears <- yip(from=start(z), to=end(z), out.type="nmbr" )</pre>
m <- monthlyfunction(z, FUN=sum)</pre>
```

Another way of computing the sum of the monthly values in each station of 'x'
This way is usefult for posteriori boxplots

74

OcaEnOnaQts

```
m2 <- monthlyfunction(x, FUN=sum, dates=1, out.type="db")
## Average monthly precipitation in each station of 'x'
m2$Value <- m2$Value / nyears
## Creating monthly factors
m2$Month <- factor(m2$Month, levels=month.abb)
## boxplot of the monthly values in all stations
boxplot(Value ~ Month, m2, col="lightyellow", main="Monthly Precipitation, [mm/month]")
## End(Not run)</pre>
```

OcaEnOnaQts

Oca in "Ona" (Q0931), time series of daily streamflows.

Description

Time series with daily streamflows of the Oca River (subcatchment of the Ebro River basin, Spain) measured at the gauging station "Ona" (Q093), for the period 01/Jan/1961 to 31/Dic/1963

Usage

data(OcaEnOnaQts)

Format

zoo object.

Source

Downloaded from the web site of the Confederacion Hidrografica del Ebro (CHE) http://www.chebro.es/ (original link http://oph.chebro.es/documentacion/CaudalEA/CaudalEA.htm, last accessed [March 2010]).

These data are intended to be used for research purposes only, being distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY.

plot_pq

Description

Given a time series of precipitation and streamflow, this function plots the two time series in the same figure, streamflows as a normal time series and preciitation as bars comming from the upper part of the plotting window.

Usage

```
plot_pq(p, ...)
## S3 method for class 'zoo'
plot_pq(p, q, ptype=c("original", "monthly"),
                na.fill=c("remove", "linear", "spline"),
                from=start(p), to=end(p), date.fmt=NULL, tz=NULL,
                main=ifelse(ptype=="original", "Precipitation and Streamflows",
                             "Monthly Precipitation and Streamflows"),
                xlab=ifelse(ptype=="original", "Time", "Month"),
                ylab=c("P, [mm]", "Q, [m3/s]"),
                p.col=ifelse(ptype=="original", "blue", "lightblue"),
                q.col=ifelse(ptype=="original", "black", "blue"),
                leg.title="", leg.text=c("P", "Q"),
                q.pch=16, q.cex=0.3,
                start.month=1,
                plot.p.probs=TRUE, p.probs=c(0.25, 0.75),
                p.alpha=0.8,
                plot.q.probs=TRUE, q.probs=c(0.25, 0.75),
                q.probs.col="lightskyblue1", q.probs.alpha=0.8,
                labels=TRUE, labels.cex=0.8,
                labels.p.dy=-median(daily2monthly(p, FUN=sum, na.rm=TRUE),
                             na.rm=TRUE)*1.1,
                labels.q.dx=c(rep(-0.2,6), rep(0.2,6)),
                labels.q.dy=rep(median(q, na.rm=TRUE)*1.3, 12),
                ...)
```

Arguments

р	zoo object with precipitation time series, with any time frequency.
q	zoo object with streamflow time series, with any time frequency.
ptype	Character indicating the type of plot to be produced. Valid values are:
	-) original => a time series plot with precipitation in the upper panel (as bars

	from the time axis) and streamflows in the lower pannel (as dotted lines). -) monthly => a plot with mean monthly values of pecipitation in the upper
	panel (as bars from top to bottom) and streamflows in the lower panel (as bars from bottom to up). Quantiles of precipitation and streamflows are also plotted depending on the values defined in p.probs and q.probs, respectively.
na.fill	Character indicating how to fill any NA present in x. Valid values are: -) remove => NAs are not plotted -) linear => NAs are removed by linear interpolation, using na.approx -) spline => NAs are removed by spline interpolation, using na.spline
from	Character indicating the starting date for subsetting p and q. The default value corresponds to the date of the first element of p It has to be in the format indicated by date.fmt.
to	Character indicating the ending date for subsetting p and q. The default value corresponds to the date of the last element of p It has to be in the format indicated by date.fmt.
date.fmt	character indicating the format in which the dates are stored in from and to, e.g. %Y-%m-%d. See 'Details' section in strptime. By default, date.fmt is missing, and it is automatically set to %Y-%m-%d when time(x) is Date object, and set to %Y-%m-%d %H:%M:%S when x is a sub-daily zoo object.
tz	character, with the specification of the time zone used for from, to. System- specific (see time zones), but "" is the current time zone, and "GMT" is UTC (Universal Time, Coordinated). See Sys.timezone and as.POSIXct.
	If tz is missing (the default), it is automatically set to the time zone used in time(x).
	This argument can be used when working with sub-daily zoo objects to force using time zones other than the local time zone for from and to. It should be used with caution, being well aware of the time zone of the data. See examples.
main	The main title (on top) of the figure.
xlab	a title for the x axis. See title.
ylab	a two-element title for the y axis: see title. The first element is used for the right y axis (i.e., for precipitation). The second element is used for the left y axis (i.e., for streamflows).
p.col	character, representing the colors to be used for ploting the precipitation time series.
q.col	character, representing the colors to be used for ploting the streamflow time series.
leg.title	a character string or length-one expression giving a title to be placed at the top of the legend. legend.
leg.text	a two-element character to appear in the legend placed at the bottom of the figure. The first element is used for precipitation and the second element is used for streamflows.

q.pch	numeric, representing the symbols used for ploting the streamflow time series.
q.cex	a numerical vector giving the amount by which plotting characters and symbols should be scaled relative to the default. This works as a multiple of par("cex"). See plot.default
start.month	numeric in [1:12] indicating the starting month for the monthlycurve. Numeric values in [1, 12] represents months in [January, December]. By default start.month=1.
plot.p.probs	logical used to decide whether to show lower an upper uncertainty values for each one of the 12 monthly precipitation values. By default plot.p.probs=TRUE. When plot.p.probs=TRUE the p.probs argument is used to define the values of the lower an upper uncertainty values.
p.probs	numeric of length 2. It defines the quantile values used to compute the lower an upper uncertainty values for each one of the 12 monthly precipitation values. This uncertainty values are drawn as vertical lines over the bars used to plot the 12 monthly precipitation values. By default p.probs=c(0.25, 0.75), which indicates that the quantiles 0.25 and 0.75 are used to compute the lower an upper uncertainty bounds for each one of the 12 monthly precipitation values. If p is a (sub)daily zoo object, it is first aggregated into monthly values using mean, and then the p.probs quantiles are computed over all the monthly values belonging to a calendar month.
p.alpha	numeric of length 1, with the factor used to modify the opacity of p.col. Typically in [0,1], with 0 indicating a completely transparent colour and 1 indicating no transparency.
plot.q.probs	logical used to decide whether to show uncertainty bands around each one of the 12 monthly average or median streamflow values. By default plot.q.probs=TRUE. When plot.q.probs=TRUE the q.probs argument is used to define the values of the lower an upper uncertainty bands.
q.probs	numeric of length 2. It is used to define quantile values used to compute the lower an upper uncertainty bands around each one of the 12 monthly average or median streamflow. If pcp is provided, then ubands.probs are used to compute the lower an upper uncertainty bounds for each one of the 12 monthly average or median precipitation values. By default ubands.probs= $c(0.25, 0.75)$, which indicates that the quantiles 0.25 and 0.75 are used to compute the lower an upper uncertainty bounds for each one of the 12 monthly average or median values. If x is provided and is a (sub)daily zoo object, it is first aggregated into monthly values using FUN, and then the ubands.probs quantiles are computed over all the monthly values belonging to a calendar month.
q.probs.col	character with the color used to plot the uncertainty bands around the average or median streamflow values.
q.probs.alpha	numeric of length 1, with the factor used to modify the opacity of q.probs.col. Typically in [0,1], with 0 indicating a completely transparent colour and 1 indi- cating no transparency.

plot_pq

labels	logical. Should monthly streamflow values to be shown above the lines?. By default labels=TRUE.
labels.cex	numeric giving the amount by which plotting characters used to show the nu- meric values of monthly streamflow values are scaled relative to the default.
labels.p.dy	numeric of length 12 giving the amount of vertical coordinate positions that have to be used to vertically shift the labels of monthly precipitation values. It is only used when labels=TRUE. Lengths smaller than 12 are recycled and larger lengths are not used.
labels.q.dx	numeric of length 12 giving the amount of horizontal coordinate positions that have to be used to horizontally shift the labels of monthly streamflow values. It is only used when labels=TRUE. Lengths smaller than 12 are recycled and larger lengths are not used.
labels.q.dy	numeric of length 12 giving the amount of vertical coordinate positions that have to be used to vertically shift the labels of monthly streamflow values. It is only used when labels=TRUE. Lengths smaller than 12 are recycled and larger lengths are not used.
	further arguments passed to or from other methods. Not used yet.

Details

Given a time series of precipitation and streamflow, this function plots the two time series in the same figure, streamflows as a normal time series and precipitation as bars comming from the upper part of the plotting window.

Value

A figure with the two time series in the same graphical area, streamflows as a normal time series and precipitation as bars comming from the upper part of the plotting window.

Remove First Character(s)

Description

Deletes the first n character(s) of a character object.

Usage

rm1stchar(x, n = 1)

Arguments

х	Character, e.g, each element may represent the name of a single gauging station.
n	numeric, indicating the number of characters that have to be removed from the beginning of x

Value

character object of the same length as x.

seasonalfunction Seasonal Function

Description

Generic function for applying any R function to a zoo object, in order to obtain 4 representative seasonal values.

Usage

Arguments

x	zoo, data.frame or matrix object, with daily or monthly time series. Measurements at several gauging stations can be stored in a data.frame of matrix object, and in that case, each column of x represent the time series measured in each gauging station, and the column names of x have to correspond to the ID of each station (starting by a letter).
FUN	Function that will be applied to ALL the values in x belonging to each one of the 4 weather seasons (e.g., FUN can be some of mean, max, min, sd).
na.rm	Logical. Should missing values be removed before the computations? -) TRUE : the monthly values are computed considering only those values in x different from NA (very important when FUN=sum) -) FALSE: if there is AT LEAST one NA within a month, the FUN and monthly values are NA
type	<pre>character, indicating which weather seasons will be used for computing the out- put. Possible values are: -) default => "winter"= Dec, Jan, Feb; "spring"= Mar, Apr, May; "summer"=Jun, Jul, Aug; "autumn"= Sep, Oct, Nov -) FrenchPolynesia => "winter"= Dec, Jan, Feb, Mar; "spring"= Apr, May; "summer"=Jun, Jul, Aug, Sep; "autumn"= Oct, Nov</pre>
dates	 numeric, factor, Date indicating how to obtain the dates. If dates is a number (default), it indicates the index of the column in x that stores the dates If dates is a factor, it is converted into Date class, by using the date format specified by date.fmt If dates is already of Date class, the code verifies that the number of days in dates be equal to the number of element in x

82

date.fmt	Character indicating the format in which the dates are stored in dates, e.g. %Y-%m-%d. See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric".
out.type	 Character defining the desired type of output. Valid values are: -) data.frame: a data.frame, with 4 columns representing the weather seasons, and as many rows as stations are included in x -) db : a data.frame, with 4 colums will be produced. Useful for a posterior boxplot The first column (StationID) will store the ID of the station, The second column (Year) will store the year, The third column (Season) will store the season, The fourth column (Value) will contain the seasonal value corresponding to that year and that station.
verbose	Logical; if TRUE, progress messages are printed
	further arguments passed to or from other methods

Warning

The FUN value for the winter season (DJF) is computed considering the consecutive months of December, January and February. Therefore, if x starts in January and ends in December of any year, the winter value of the first year is computed considering only the January and February value of that year, whereas the December value of the first year is used to compute the winter value of the next year.

Note

FUN is applied to all the values of x belonging to each one of the four weather seasons, so the results of this function depends on the frequency sampling of x and the type of function given by FUN

See Also

dm2seasonal, time2season, monthlyfunction, annualfunction, extract

Examples

```
## Loading the SanMartino precipitation data
data(SanMartinoPPts)
x <- SanMartinoPPts
# Amount of years
nyears <- yip(from=start(x), to=end(x), out.type="nmbr")
## Mean annual precipitation.
# It is precessory to divide by the appunt of years to obtain the mean appual</pre>
```

It is necessary to divide by the amount of years to obtain the mean annual value,

sfreq

Sampling Frequency

Description

This function identifies the sampling frequency of a zoo object. It is wrapper to the periodicity function of the **xts** package.

Usage

sfreq(x, min.year = 1800)

Arguments

Х	variable of type zoo, xts or ts, with AT LEAST 2 elements, AND with a (sub)hourly,
	hourly, daily, weekly, monthly, quarterly, or annual (yearly) sampling frequency.
min.year	integer used for a correct identification of the sampling frequency when x is an annual (yearly) time series.

Details

See further details in the periodicity function of the xts package.

Value

Character. Possible values are:

-) minute : indicating that the sampling frequency in x is sub-hourly

-) hourly : indicating that the sampling frequency in x is hourly

-) daily : indicating that the sampling frequency in x is daily

sfreq

- -) weekly : indicating that the sampling frequency in x is weekly
- -) monthly : indicating that the sampling frequency in x is monthly
- -) quarterly : indicating that the sampling frequency in x is quarterly
- -) annual : indicating that the sampling frequency in \boldsymbol{x} is annual

```

```
## Ex5: Annual data
a <- daily2annual(d, FUN=mean, na.rm=TRUE)
sfreq(a)</pre>
```

Description

Function to compute the seasonality index defined by Walsh and Lawler (1981) to classify the precipitation regime.

Usage

si(x, na.rm=TRUE, from=start(x), to=end(x), date.fmt="%Y-%m-%d", start.month=1)

Arguments

	o object with daily or subdaily precipitation data.
-) en -)	ogical. Should missing values be removed? TRUE : the monthly values are computed considering only those values differ- tt from NA FALSE: if there is AT LEAST one NA within a month, the resulting average onthly value is NA.
Ch	PTIONAL, used for extracting a subset of values. haracter indicating the starting date for the values to be extracted. It must be ovided in the format specified by date.fmt.
Ch	PTIONAL, used for extracting a subset of values. haracter indicating the ending date for the values to be extracted. It must be ovided in the format specified by date.fmt.
to	haracter indicating the format in which the dates are stored in <i>dates</i> , <i>from</i> and . See format in as.Date. NLY required when class(dates)=="factor" or class(dates)=="numeric".
	OPTIONAL]. Only used when the (hydrological) year of interest is different on the calendar year.
m	meric in [1:12] indicating the starting month of the (hydrological) year. Nu- eric values in [1, 12] represents months in [January, December]. By default cart.month=1.

Details

The seasonality index is computed as following:

si = (1/R) *sum(i=1, i=12, abs(xi - R/12))
where:
-) xi: mean monthly precipitation for month i
-) R: mean annual precipitation

si

This index can theoretically vary from 0 (when all months have the same rainfall) to 1.83 (when all the rainfall ocurrs in a single month). A qualitative classification of degrees of seasonality is the following:

si values | Rainfall regime

<= 0.19 | Very equable

0.20 - 0.39 | Equable but with a definite wetter season

0.40 - 0.59 | Rather seasonal with a short drier season

0.60 - 0.79 | Seasonal

0.80 - 0.99 | Markedly seasonal with a long drier season

1.00 - 1.19 | Most rain in 3 months or less

>= 1.20 | Extreme, almost all rain in 1-2 months

Value

numeric with the seasonality index

Author(s)

Mauricio Zambrano-Bigiarini, <mzb.devel@gmail>

smry

Summary

Description

Extended summary function for numeric objects, with 13 summary statistics.

smry

Usage

```
smry(x, ...)
## Default S3 method:
smry(x, na.rm=TRUE, digits = max(3, getOption("digits")-3), ...)
## S3 method for class 'zoo'
smry(x, na.rm=TRUE, digits = max(3, getOption("digits")-3), ...)
## S3 method for class 'Date'
smry(x, na.rm=TRUE, digits = max(3, getOption("digits")-3), ...)
## S3 method for class 'matrix'
smry(x, na.rm=TRUE, digits = max(3, getOption("digits")-3), ...)
## S3 method for class 'data.frame'
smry(x, na.rm=TRUE, digits = max(3, getOption("digits")-3), ...)
```

Arguments

х	a numeric object, vector, matrix or data.frame, for which a summary is desired.
na.rm	a logical value indicating whether 'NA' values should be stripped before the computation proceeds.
digits	numeric, with the amount of decimal places to be included in the result
	further arguments passed to or from other methods.

Value

Computed summary statistics are:

Min	Minimum
1stQ	First quartile (lower-hinge)
Mean	Mean value
Median	Median
3rdQ	Third quartile (upper-hinge
Max	Maximum of the input values.
IQR	<pre>Interquartile Range. IQR(x) = quantile(x,3/4) - quantile(x,1/4)</pre>
sd	Standard deviation. It uses 'n-1' as denominator.
CV	Coefficient of variation (cv= sd / mean)
skewness	Skewness (using e1071 package)
kurtosis	Kurtosis (using e1071 package)
n	Total number of elements
NA's	Amount of missing values

sname2ts

Note

Skewness and Kurtosis are computed with the e1071 package

Station Name -> Time Series

Description

This function takes a data.frame whose columns contains the time series of several gauging stations, along with a character representing the name of one gauging station, and extracts the time series corresponding to that station.

Usage

Arguments

x	data.frame containing the complete times series of all the stations. It may also contain 1 column with the dates of the measurements, or they can be provided in a different way (see dates below).
sname	Character representing the name of a station, which have to correspond to one column name in \boldsymbol{x}
dates	 numeric, factor, Date object indicating how to obtain the dates corresponding to the sname station. -) If dates is a number (default), it indicates the index of the column in x that stores the dates -) If dates is a factor, it is converted into Date class, using the date format specified by date.fmt -) If dates is already of Date class, the code verifies that the number of days in dates be equal to the number of element in x

sname2ts

date.fmt	character indicating the format in which the dates are stored in <i>dates</i> , e.g. %Y-%m-%d. See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric".
var.type	<pre>character representing the type of variable being plotted. Used for determining the function used for computing the monthly or/and annual values when FUN is missing. Valid values are: -) Precipitation => FUN=sum -) Temperature => FUN= mean -) Flow => FUN= mean</pre>
tstep.out	<pre>character that defines the time step of the desired output time series. Valid values are: -) daily : daily time series -) monthly: monthly time series -) annual : annual time series</pre>
FUN	ONLY required when var.type is missing and tstep is one of monthly or annual. Function that have to be applied for transforming from daily to monthly or an- nual time step (e.g., for precipitation FUN=sum and for temperature and flow ts, FUN=mean)
na.rm	a logical value indicating whether 'NA' values should be stripped before the computation proceeds.
from	OPTIONAL, used for extracting a subset of values. Character indicating the starting date for the values to be extracted. It must be provided in the format specified by date.fmt.
to	OPTIONAL, used for extracting a subset of values. Character indicating the ending date for the values to be extracted. It must be provided in the format specified by date.fmt.

Value

zoo object

Examples

Loading the monthly time series of precipitation within the Ebro River basin. data(EbroPPtsMonthly)

Annual values of temperature at the station "T9105", stored in 'EbroPPtsMonthly'. sname2ts(EbroPPtsMonthly, sname="P9001", dates=1, FUN=sum, tstep.out="annual") stdx

Description

Standarizes a vector or matrix, i.e., scales all the values in a way that the transformed values will be within the range [0, 1].

Usage

stdx(x, ...)

Arguments

х	vector, matrix or data.frame to be scaled
•••	further arguments passed to or from other methods

Details

$$z = \frac{x - x_{min}}{x_{max} - x_{min}}$$

```

Description

Generic function for transforming a Sub-DAILY time series into a DAILY one

Usage

```
subdaily2daily(x, ...)
## Default S3 method:
subdaily2daily(x, FUN, na.rm = TRUE, na.rm.max=0,
                       start="00:00:00", start.fmt= "%H:%M:%S", tz, ...)
## S3 method for class 'zoo'
subdaily2daily(x, FUN, na.rm = TRUE, na.rm.max=0,
                       start="00:00:00", start.fmt= "%H:%M:%S", tz, ...)
## S3 method for class 'data.frame'
subdaily2daily(x, FUN, na.rm = TRUE, na.rm.max=0,
           start="00:00:00", start.fmt= "%H:%M:%S", tz,
           dates=1, date.fmt="%Y-%m-%d %H:%M:%S", out.fmt="zoo",
           verbose= TRUE, ...)
## S3 method for class 'matrix'
subdaily2daily(x, FUN, na.rm = TRUE, na.rm.max=0,
           start="00:00:00", start.fmt= "%H:%M:%S", tz,
           dates=1, date.fmt="%Y-%m-%d %H:%M:%S", out.fmt="zoo",
           verbose= TRUE, ...)
```

Arguments

x	zoo, data.frame or matrix object, with sub-daily time series. Measurements at several gauging stations can be stored in a data.frame or matrix object, and in that case, each column of x represents the time series measured in each gauging station, and the column names of x should correspond to the ID of each station (starting by a letter).
FUN	Function that have to be applied for aggregating from sub-daily into daily time step (e.g., for precipitation FUN=sum and for temperature and streamflows ts FUN=mean).
	FUN MUST accept the na.rm argument, because na.rm is passed to FUN.
na.rm	Logical. Should missing values be removed? -) TRUE : the daily values are computed only for days with a percentage of miss- ing values less than na.rm.max

	-) FALSE: if there is AT LEAST one NA within a day, the corresponing daily value in the output object will be NA.
na.rm.max	Numeric in [0, 1]. It is used to define the maximum percentage of missing values allowed in each day to keep the daily aggregated value in the output object of this function. In other words, if the percentage of missing values in a given day is larger or equal than na.rm.max the corresponding daily value will be NA.
start	 character, indicating the starting time used for aggregating sub-daily time series into daily ones. It MUST be provided in the format specified by start.fmt. This value is used to define the time when a new day begins (e.g., for some rain gauge stations). -) All the values of x with a time attribute before start are considered as belonging to the day before the one indicated in the time attribute of those values. -) All the values of x with a time attribute equal to start are considered to be equal to "00:00:00" in the output zoo object. -) All the values of x with a time attribute after start are considered as belonging to the same day as the one indicated in the time attribute of those values.
	with caution. See examples.
start.fmt	character indicating the format in which the time is provided in start, By de-fault date.fmt=%H:%M:%S. See format in as.POSIXct.
tz	character, with the specification of the time zone used in both x and start. System-specific (see time zones), but "" is the current time zone, and "GMT" is UTC (Universal Time, Coordinated). See Sys.timezone and as.POSIXct. If tz is missing (the default), it is automatically set to the time zone used in time(x). This argument can be used to force using the local time zone or any other time zone instead of UTC as time zone.
dates	 numeric, factor, POSIXct or POSIXt object indicating how to obtain the dates and times for each column of x (e.g., gauging station) If dates is a number, it indicates the index of the column in x that stores the date and times If dates is a factor, it is converted into POSIXct class, using the date format specified by date.fmt If dates is already of POSIXct or POSIXt class, the code verifies that the number of elements on it be equal to the number of elements in x
date.fmt	character indicating the format in which the dates are stored in dates, By de- fault date.fmt=%Y-%m-%d %H:%M:%S. See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric".
out.fmt	OPTIONAL. Only used when x is a matrix or data.frame object /cr character, for selecting if the result will be a matrix/data.frame or a zoo object. Valid values are: numeric, zoo (default)
verbose	logical; if TRUE, progress messages are printed
	arguments additional to na.rm passed to FUN.

```

subdaily2weekly Subdaily -> Weekly

Description

Generic function for transforming a DAILY (or sub-daily) regular time series into a WEEKLY one

Usage

```
subdaily2weekly(x, ...)
## Default S3 method:
subdaily2weekly(x, FUN, na.rm=TRUE, na.rm.max=0,
           start="00:00:00", start.fmt= "%H:%M:%S", tz, ...)
## S3 method for class 'zoo'
subdaily2weekly(x, FUN, na.rm=TRUE, na.rm.max=0,
           start="00:00:00", start.fmt= "%H:%M:%S", tz, ...)
## S3 method for class 'data.frame'
subdaily2weekly(x, FUN, na.rm=TRUE, na.rm.max=0,
           start="00:00:00", start.fmt= "%H:%M:%S", tz,
           dates=1, date.fmt = "%Y-%m-%d %H:%M:%S",
           out.fmt="zoo", verbose=TRUE, ...)
## S3 method for class 'matrix'
subdaily2weekly(x, FUN, na.rm=TRUE, na.rm.max=0,
           start="00:00:00", start.fmt= "%H:%M:%S", tz,
           dates=1, date.fmt = "%Y-%m-%d %H:%M:%S",
           out.fmt="zoo", verbose=TRUE, ...)
```

Arguments

x	zoo, data.frame or matrix object, with (sub)daily time series. Measurements at several gauging stations can be stored in a data.frame or matrix object, and in that case, each column of x represents the time series measured in each gauging station, and the column names of x have to correspond to the ID of each station (starting by a letter).
FUN	Function that have to be applied for transforming from daily to weekly time step (e.g., for precipitation FUN=sum and for temperature and streamflow ts FUN=mean).
	FUN MUST accept the na.rm argument, because na.rm is passed to FUN.
na.rm	Logical. Should missing values be removed? -) TRUE : the weekly values are computed only for weeks with a percentage of missing values less than na.rm.max -) FALSE: if there is AT LEAST one NA within a month, the corresponing weekly values in the output object will be NA.

na.rm.max	Numeric in [0, 1]. It is used to define the maximum percentage of missing values allowed in each month to keep the weekly aggregated value in the output object of this function. In other words, if the percentage of missing values in a given month is larger or equal than na.rm.max the corresponding weekly value will be NA.
start	 character, indicating the starting time used for aggregating sub-daily time series into daily ones. It MUST be provided in the format specified by start.fmt. This value is used to define the time when a new day begins (e.g., for some rain gauge stations). -) All the values of x with a time attribute before start are considered as belonging to the day before the one indicated in the time attribute of those values. -) All the values of x with a time attribute equal to start are considered to be equal to "00:00:00" in the output zoo object. -) All the values of x with a time attribute after start are considered as belonging to the same day as the one indicated in the time attribute of those values.
	It is useful when the daily values start at a time different from "00:00:00". Use with caution. See examples.
start.fmt	character indicating the format in which the time is provided in start, By de-fault date.fmt=%H:%M:%S. See format in as.POSIXct.
tz	character, with the specification of the time zone used in both x and start. System-specific (see time zones), but "" is the current time zone, and "GMT" is UTC (Universal Time, Coordinated). See Sys.timezone and as.POSIXct. If tz is missing (the default), it is automatically set to the time zone used in time(x). This argument can be used to force using the local time zone or any other time zone instead of UTC as time zone.
dates	numeric, factor or Date object indicating how to obtain the dates for each gaug- ing station If dates is a number (default), it indicates the index of the column in x that stores the dates If dates is a factor, it is converted into Date class, using the date format speci- fied by date.fmt If dates is already of Date class, the code verifies that the number of days on it be equal to the number of elements in x
date.fmt	character indicating the format in which the DateTime objects are stored in <i>dates</i> , e.g. %Y-%m-%d %H:%M:%S. See format in as.POSIXct. ONLY required when class(dates)=="factor" or class(dates)=="numeric".
out.fmt	OPTIONAL. Only used when x is a matrix or data.frame object /cr character, for selecting if the result will be a matrix/data.frame or a zoo object. Valid values are: numeric, zoo.
verbose	logical; if TRUE, progress messages are printed
	arguments additional to na.rm passed to FUN.

Value

a zoo object with weekly time frequency

subhourly2hourly Sub-hourly -> Hourly

Description

Generic function for transforming a sub-HOURLY time series into an HOURLY one

Usage

Arguments

x	zoo, data.frame or matrix object, with sub-hourly time series. Measurements at several gauging stations can be stored in a data.frame or matrix object, and in that case, each column of x represent the time series measured in each gauging station, and the column names of x represent the ID of each station.
FUN	Function that have to be applied for transforming from sub-hourly to hourly time step. (e.g., for precipitation FUN=sum and for temperature and streamflow ts, FUN=mean).
na.rm	 Logical. Should missing values be removed? -) TRUE : the hourly values are computed considering only those values different from NA -) FALSE: if there is AT LEAST one NA sub-hourly value within a day, the corresponding hourly value(s) will be NA as well

Numeric in [0, 1]. It is used to define the maximum percentage of missing values allowed in each hour to keep the hourly aggregated value in the output object of this function. In other words, if the percentage of missing values in a given hour is larger or equal than na.rm.max the corresponding hourly value will be NA.
numeric, factor, POSIXct or POSIXt object indicating how to obtain the dates and times for each column of x (e.g., gauging station) If dates is a number, it indicates the index of the column in x that stores the date and times
If dates is a factor, it is converted into POSIXct class, using the date format specified by date.fmt If dates is already of POSIXct or POSIXt class, the code verifies that the number of elements on it be equal to the number of elements in x
character indicating the format in which the dates are stored in dates, By de- fault date.fmt=%Y-%m-%d%H:%M:%S. See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric".
OPTIONAL. Only used when x is a matrix or data.frame object /cr character, for selecting if the result will be a matrix/data.frame or a zoo object. Valid values are: numeric, zoo (default)
logical; if TRUE, progress messages are printed
further arguments passed to or from other methods.

Value

a zoo object with hourly time series

Author(s)

Mauricio Zambrano-Bigiarini, <mzb.devel@gmail>

Examples

```
## Creating a 15-min time sequence and counting its length
dt <- seq( from=as.POSIXct("2021-06-30 00:15"), to=as.POSIXct("2021-06-30 23:45"), by="15 min" )
ndt <- length(dt)
## Creating a dummy 15-min zoo object, with 1 as the only value in each time period
x <- zoo( rep(1, ndt), dt)
## sub-hourly to hourly
h1 <- subhourly2hourly(x, FUN=sum, na.rm=TRUE)
## Aggregation of 3 sub-hourly ts (i.e., a zoo matrix) into an hourly one
X <- cbind(x, x, x)
h2 <- subhourly2hourly(X, FUN=sum, na.rm=TRUE)</pre>
```

subhourly2nminutes Sub-hourly -> n-minutes

Description

Generic function for aggregating a sub-hourly time series into a "n-minutes' one.

Usage

Arguments

x	zoo, data.frame or matrix object, with sub-hourly time series. Measurements at several gauging stations can be stored in a data.frame or matrix object, and in that case, each column of x represent the time series measured in each gauging station, and the column names of x represent the ID of each station.
nminutes	numeric, defining the amount of minutes to be used for aggregating x. nminutes must be larger than the amount of minutes between each x value (computed as $time(x)[2]-time(x)[1]$).
FUN	Function that have to be applied for aggregating from sub-hourly into n-minutes time step. (e.g., for precipitation FUN=sum and for temperature and streamflow ts, FUN=mean).
na.rm	Logical. Should missing values be removed? -) TRUE : the hourly values are computed considering only those values different from NA -) FALSE: if there is AT LEAST one NA sub-hourly value within a day, the corresponding hourly value(s) will be NA as well

from	POSIX object indicating the starting time used to carry out the temporal aggre- gation.
	When from > start(x) then x is cut in time to the starting DateTime defined by from.
	When from < start(x) then x is extended backward with NAs to the starting DateTime defined by from.
to	POSIX object indicating the ending time used to carry out the temporal aggre- gation.
	When to $< end(x)$ then x is cut in time to the ending DateTime defined by to. When to $> end(x)$ then x is extended forward with NAs to the ending DateTime defined by from.
dates	numeric, factor, POSIXct or POSIXt object indicating how to obtain the dates and times for each column of x (e.g., gauging station)
	If dates is a number, it indicates the index of the column in x that stores the date and times
	If dates is a factor, it is converted into POSIXct class, using the date format specified by date.fmt
	If dates is already of POSIXct or POSIXt class, the code verifies that the num- ber of elements on it be equal to the number of elements in x
date.fmt	character indicating the format in which the dates are stored in dates, By de- fault date.fmt=%Y-%m-%d %H:%M:%S. See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric"
out.fmt	OPTIONAL. Only used when x is a matrix or data.frame object /cr character, for selecting if the result will be a matrix/data.frame or a zoo object. Valid values are: numeric, zoo (default)
verbose	logical; if TRUE, progress messages are printed
	further arguments passed to or from other methods.

Value

a zoo object with hourly time series

dt <- seq( from=as.POSIXct("2021-06-30 00:00"), to=as.POSIXct("2021-06-30 23:55"), by="5 min" )
ndt <- length(dt)</pre>
```

Creating a dummy 5-min zoo object, with 1 as the only value in each time period

time2season

```
x <- zoo( rep(1, ndt), dt)
## Aggregation from 5-minute single ts into 10-minute ts
h1 <- subhourly2nminutes(x, nminutes= 10, FUN=sum, na.rm=TRUE)
## Aggregation of 3 ts with 5-minute time frequency (i.e., a zoo matrix)
## into a 30-minute zoo object.
X <- cbind(x, x, x)
h2 <- subhourly2nminutes(X, nminutes= 30, FUN=sum, na.rm=TRUE)</pre>
```

time2season Date/DateTime character -> Seasonal character

Description

This function transforms a character vector of Dates or DateTimes into a character vector of seasons (summer, winter, autumn, spring), depending on the value of type:

When type=default -) winter = DJF: December, January, February

- -) spring = MAM: March, April, May
- -) summer = JJA: June, July, August
- -) autumn = SON: September, October, November

When type=FrenchPolynesia -) winter = DJFM: December, January, February, March

- -) spring = AM : April, May
- -) summer = JJAS: June, July, August, September
- -) autumn = ON : October, November

Usage

time2season(x, out.fmt = "months", type="default")

Arguments

x	vector with the dates that have to be transformed. $class(x)$ must be Date
out.fmt	<pre>character, indicating the format of the output seasons. Possible values are: -) seasons => c("winter", "spring", "summer", autumn") -) months => c("DJF", "MAM", "JJA", SON") or c("DJFM", "AM", "JJAS", ON")</pre>
type	<pre>character, indicating which weather seasons will be used for computing the out- put. Possible values are: -) default => "winter"= Dec, Jan, Feb; "spring"= Mar, Apr, May; "summer"=Jun, Jul, Aug; "autumn"= Sep, Oct, Nov -) FrenchPolynesia => "winter"= Dec, Jan, Feb, Mar; "spring"= Apr, May; "summer"=Jun, Jul, Aug, Sep; "autumn"= Oct, Nov</pre>

Value

character vector with the weather season to which each date in x belongs

Note

Weather seasons corresponding to French Polynesia were defined following a comment from Lydie Sichoix

Author(s)

Mauricio Zambrano-Bigiarini, <mzb.devel@gmail>

Examples

```
## Sequence of daily dates between "1961-01-01" and "1961-12-31"
t <- dip("1961-01-01", "1961-12-31")
time2season(t)
## Sequence of monthly dates between "1961-01-01" and "1961-12-31"
t <- mip("1961-01-01", "1961-12-31")
time2season(t)
time2season(t, out.fmt="seasons")</pre>
```

vector2zoo

Vector -> *Zoo*

Description

Transform a numeric vector and its corresponding dates into a zoo object.

Usage

```
vector2zoo(x, dates, date.fmt = "%Y-%m-%d")
```

Arguments

х	numeric vector
dates	character, factor, Date or POSIXct object with the dates corresponding to each element of x. Valid object class for dates are: character, factor, Date, POSIXct
date.fmt	character indicating the format in which the dates are stored in <i>dates</i> , e.g. %Y-%m-%d. See 'Details' section in strptime. ONLY required when class(dates)=="factor" or class(dates)=="character".

104

weeklyfunction

Value

a zoo object, with values given by x and time stamps given by dates

z <- vector2zoo(x, dates)</pre>
```

weeklyfunction Weekly Function

Description

Generic function for obtaining 52 weekly values of a zoo object, by applying any R function to ALL the values in the object belonging to each one of the 52 calendar weeks (starting on Monday).

Usage

Arguments

x	zoo, xts, data.frame or matrix object, with daily or monthly time series. Measurements at several gauging stations can be stored in a data.frame of matrix object, and in that case, each column of x represent the time series measured in each gauging station, and the column names of x have to correspond to the ID of each station (starting by a letter).
FUN	Function that will be applied to ALL the values in x belonging to each one of the 12 months of the year (e.g., FUN can be some of mean, sum, max, min, sd).
na.rm	Logical. Should missing values be removed? -) TRUE : the monthly values and FUN are computed considering only those values in x different from NA -) FALSE: if there is AT LEAST one NA within a month, the corresponding monthly value will be NA
na.rm.max	Numeric in [0, 1]. It is used to define the maximum percentage of missing values allowed in each month to keep the weekly aggregated value in the output object of this function. In other words, if the percentage of missing values in a given month is larger or equal than na.rm.max the corresponding weekly value will be NA.
start	 character, indicating the starting time used for aggregating sub-daily time series into daily ones. It MUST be provided in the format specified by start.fmt. This value is used to define the time when a new day begins (e.g., for some rain gauge stations). -) All the values of x with a time attribute before start are considered as belonging to the day before the one indicated in the time attribute of those values. -) All the values of x with a time attribute equal to start are considered to be

106

	equal to "00:00:00" in the output zoo object. -) All the values of x with a time attribute after start are considered as belong- ing to the same day as the one indicated in the time attribute of those values.
	It is useful when the daily values start at a time different from "00:00:00". Use with caution. See examples.
start.fmt	character indicating the format in which the time is provided in start, By de- fault date.fmt=%H:%M:%S. See format in as.POSIXct.
tz	character, with the specification of the time zone used in both x and start.System-specific (see time zones), but "" is the current time zone, and "GMT" is UTC (Universal Time, Coordinated). See Sys.timezone and as.POSIXct.If tz is missing (the default), it is automatically set to the time zone used in time(x).This argument can be used to force using the local time zone or any other time zone instead of UTC as time zone.
dates	It is only used when x is not a zoo object. numeric, factor, Date indicating how to obtain the dates. If dates is a number (default), it indicates the index of the column in x that stores the dates If dates is a factor, it is converted into 'Date' class, using the date format spec- ified by date.fmt If dates is already of Date class, the code verifies that the number of days in dates be equal to the number of elements in x
date.fmt	It is only used when x is not a zoo object. character indicating the format in which the dates are stored in <i>dates</i> , e.g. %Y-%m-%d. See format in as.Date. ONLY required when class(dates)=="factor" or class(dates)=="numeric".
out.type	 It is only used when x is a matrix or data.frame. Character defining the desired type of output. Valid values are:) data.frame: a data.frame, with 12 columns representing the months, and as many rows as gauging stations are included in x) db : a data.frame, with 4 columns will be produced. Useful for a posterior boxplot The first column ('StationID') will store the ID of the station, The second column ('Year') will store the year, The third column ('Month') will store month, The fourth column ('Value') will contain the monthly value corresponding to the three previous columns.
verbose	Logical; if TRUE, progress messages are printed
	further arguments passed to or from other methods

Value

When x is a zoo object, a numeric vector with 12 elements representing the computed monthly value for each month.

When x is a data.frame which columns represent measurements at different gauging stations, the

resulting object is a data.frame with 12 columns and as many rows as gauging stations are in x, each row storing the computed 12 monthly value for each gauging station.

Note

Due to the fact that FUN is applied over all the elements in x belonging to a given calendar month, its result will depend on the sampling frequency of x and the type of function provided by FUN (**special attention have to be put when** FUN=sum)

Examples

Ex1: Computation of mean WEEKLY values from DAILY ts, removing any missing value in 'x'

```
# Loading DAILY streamflows (3 years) at the station
# Oca en Ona (Ebro River basin, Spain)
data(OcaEnOnaQts)
x <- OcaEnOnaQts
## Mean WEEKLY streamflows at station 'x'
weeklyfunction(x, FUN=mean, na.rm=TRUE)
## Ex2: Computation of mean WEEKLY values from HOURLY ts, removing any missing value in 'x'
# Loading HOURLY streamflows for the station Karamea at Gorge
data(KarameaAtGorgeQts)
x <- KarameaAtGorgeQts</pre>
## Mean WEEKLY streamflows at station 'x'. Each day starts at 00:00:00
weeklyfunction(x, FUN=mean, na.rm=TRUE)
## Ex3: Computation of mean WEEKLY values from HOURLY ts, removing any missing value in 'x'
       and starting each day at 08:00:00
##
# Loading HOURLY streamflows for the station Karamea at Gorge
data(KarameaAtGorgeQts)
x <- KarameaAtGorgeQts</pre>
## Mean WEEKLY streamflows at station 'x'. Each day starts at 00:00:00
weeklyfunction(x, FUN=mean, na.rm=TRUE, start="00:00:00")
```

Description

Given any starting and ending dates, it generates:

a vector of class Date with all the years between the two dates (both of them included), OR
 the amount of years between the two dates

Usage

yip(from, to, date.fmt = "%Y-%m-%d", out.type = "seq")

Arguments

from	Character indicating the starting date for creating the sequence. It has to be in the format indicated by date.fmt.
to	Character indicating the ending date for creating the sequence. It has to be in the format indicated by date.fmt.
date.fmt	character indicating the format in which the dates are stored in from and to, e.g. %Y-%m-%d. See format in as.Date.
out.type	 Character indicating the type of result that is given by this function. Valid values are: -) seq => a vectorial sequence with all the years within the given dates. -) nmbr => the number of years within the given dates.

Value

Depending on the value of out.type, it returns:

1) seq : a vector of class Date with all the years between from and to (both of them included), OR 2) nmbr: a single numeric value with the amount of years between the two dates.

# Sequence of monthly dates between "1961-01-01" and "1961-12-31"
yip("1961-01-01", "1961-12-31")
## Computing the number of years between 1961 and 1975,
## by using "%d-%m-%Y" as date format ##
```

yip

```
yip("01-01-1961", "01-01-1975", date.fmt= "%d-%m-%Y", out.type = "nmbr")
```

zoo2RHtest Zoo -> RHTest

Description

It creates the input file to the '*RHtest_dlyPrcp.r*' script, used for testing the homogeneity of climatological time series (available at: http://etccdi.pacificclimate.org/software.shtml)

Usage

```
zoo2RHtest(x, fname="pcp.txt", tstep.out="daily", dec=".", na="-999.0")
```

Arguments

х	time series that will be written. class(x) must be a zoo object
fname	Character, with the filename of the precipitation time series
tstep.out	Character indicating the time step that have to be used for writing x into the output file
dec	the string to use for decimal points in numeric or complex columns: must be a single character.
na	character to be used for representing the missing values in the data
