Type Package

Title Hidden Markov Model for Financial Time-Series Based on Lambda Distribution

Version 0.6.1

Date 2023-12-31

Author Stephen H-T. Lihn [aut, cre]

Maintainer Stephen H-T. Lihn <stevelihn@gmail.com>

Description Hidden Markov Model (HMM) based on symmetric lambda distribution framework is implemented for the study of return time-series in the financial market. Major features in the S&P500 index, such as regime identification, volatility clustering, and anti-correlation between return and volatility, can be extracted from HMM cleanly. Univariate symmetric lambda distribution is essentially a location-scale family of exponential power distribution. Such distribution is suitable for describing highly leptokurtic time series obtained from the financial market. It provides a theoretically solid foundation to explore such data where the normal distribution is not adequate. The HMM implementation follows closely the book: ``Hidden Markov Models for Time Series'', by Zucchini, MacDonald, Langrock (2016).

ldhmm-package

ldhmm: A package for HMM using lambda distribution.

### Description

The ldhmm package provides the core class and functions to calculate Hidden Markov Model (HMM) using lambda distribution framework. The main goal is to provide a theoretically solid foundation to explore the return time-series in the financial market, where the normal distribution is not adequate due to the leptokurtic nature of the data. Major features in the S&P 500 index, such as regime identification, volatility clustering, and anti-correlation between return and volatility, can be extracted from HMM cleanly. Univariate symmetric lambda distribution is essentially a location-scale family of power-exponential distribution. Such distribution is suitable for describing highly leptokurtic time series obtained from the financial market.

### Details

The main change compared to a normal-distribution based HMM is to add the third paramter lambda to describe the kurtosis level of the distribution. When lambda is one, the model converges back to a normal-distribution based HMM (e.g. using depmixS4 package). The ability to optimize kurtosis brings the model output to be more consistent with the data. In particular, for daily data, the level of kurtosis is quite high. This puts the normal distribution in great disadvantage. This problem is solved by using the lambda distribution.

### Author(s)

Stephen H-T. Lihn

### References

Walter Zucchini, Iain L. MacDonald, Roland Langrock (2016). "Hidden Markov Models for Time Series, An Introduction Using R." Second Edition. CRC Press.

3

### Description

Construct an ecld-class by providing the required parameters. The default is the standard symmetric cusp distribution (lambda=3).

### Usage

ecld(lambda = 3, sigma = 1, mu = 0, verbose = FALSE)

# Arguments

lambda	numeric, the lambda parameter. Must be positive. Default: 3.
sigma	numeric, the scale parameter. Must be positive. Default: 1.
mu	numeric, the location parameter. Default: 0.
verbose	logical, display timing information, for debugging purpose, default is FALSE.

### Value

an object of ecld class

### Author(s)

Stephen H-T. Lihn

# Examples

```
ld <- ecld()
ld <- ecld(2, 0.01)
```

ecld-class An S4 class to represent the lambda distribution

# Description

The ecld class serves as an object-oriented interface for the lambda distribution, which is just the exponential power distribution in GSL and Wolfram.

# Slots

call the match.call slot lambda numeric sigma numeric mu numeric

### ecld

### ecld.cdf

### Details

The lambda distribution is just the exponential power distribution in GSL and Wolfram, with a different definition in the exponent of the stretched exponential function.

The distribution is symmetric. Its PDF is

$$P(x;\lambda,\sigma,\mu) \equiv \frac{1}{\lambda\Gamma\left(\frac{2}{\lambda}\right)\sigma} e^{-\left|\frac{x-\mu}{\sigma}\right|^{\frac{2}{\lambda}}}.$$

where  $\lambda$  is the shape parameter,  $\sigma$  is the scale parameter,  $\mu$  is the location parameter. This functional form is not unfamiliar and has appeared under several other names, such as generalized normal distribution and power exponential distribution, etc..

ecld.cdf

CDF and CCDF of ecld

### Description

The analytic solutions for CDF and CCDF of ecld, if available. ecld.cdf\_gamma is a sub-module with the CDF expressed as incomplete gamma function. SGED is supported only in ecld.cdf and ecld.ccdf.

#### Usage

ecld.cdf(object, x)

ecld.ccdf(object, x)

# ecld.pdf

# Arguments

object	an object of ecld class
х	a numeric vector of x

# Value

The CDF or CCDF vector

# Author(s)

Stephen H. Lihn

# Examples

```
ld <- ecld(sigma=0.01)
x <- seq(-0.1, 0.1, by=0.01)
ecld.cdf(ld,x)</pre>
```

```
ecld.pdf
```

Calculate the PDF of an ecld object

# Description

Calculate the PDF of an ecld object

# Usage

ecld.pdf(object, x)

# Arguments

object	an object of ecd class
х	numeric vector of $x$ dimension

# Value

numeric vector of the PDF

# Author(s)

Stephen H-T. Lihn

# Examples

ld <- ecld(lambda=3)
x <- seq(-10, 10, by=1)
ecld.pdf(ld,x)</pre>

ecld.sd

# Description

Compute statistics for mean, var, skewness, kurtosis.

# Usage

```
ecld.sd(object)
```

ecld.var(object)

ecld.mean(object)

ecld.skewness(object)

ecld.kurtosis(object)

ecld.kurt(object)

# Arguments

object an object of ecld class

# Value

numeric

# Author(s)

Stephen H-T. Lihn

# Examples

```
ld <- ecld(3)
ecld.sd(ld)
ecld.var(ld)
ecld.mean(ld)
ecld.skewness(ld)
ecld.kurt(ld)
```

ldhmm

# Description

Construct an ldhmm class by providing the required parameters.

# Usage

```
ldhmm(m, param, gamma, delta = NULL, stationary = TRUE, mle.optimizer = "nlm")
```

# Arguments

m	numeric, number of states
param	matrix, the ecld parameters of states.
gamma	numeric or matrix, the transition probability matrix, must be conformed to m by m. if provided as vector, it will be converted to a matrix with byrow=TRUE.
delta	numeric, the initial distribution for each state, default is NULL.
stationary	logical, specify whether the initial distribution is stationary or not, default is TRUE.
mle.optimizer	character, specify alternative optimizer, default is nlm.

# Value

An object of ldhmm class

# Author(s)

Stephen H. Lihn

# Examples

```
param0 <- matrix(c(0.003, 0.02, 1, -0.006, 0.03, 1.3), 2, 3, byrow=TRUE)
gamma0 <- matrix(c(0.9, 0.1, 0.1, 0.9), 2, 2, byrow=TRUE)
d <- ldhmm(m=2, param=param0, gamma=gamma0)</pre>
```

ldhmm-class

#### Description

This S4 class is the major object class for ldhmm package

#### Slots

call The match.call slot

m numeric, length 1, number of states

param.nbr numeric, number of parameters (2 or 3) for each ecld object

param matrix, natural parameters for ecld objects, size of states times param.nbr. Each row can be 2-parameter sequences, or 3-parameter sequences. Three-parameter unit (mu, sigma, lambda) forms an ecld object representing a leptokurtic symmetric lambda distribution. On the other hand, to provide compatibility to a normal distribution HMM, two-parameter unit (mu, sigma) forms an ecld object with lambda=1.

gamma matrix, the transition probability matrix, must be m by m.

delta numeric, the initial distribution for each state, default is NULL.

stationary logical, specify whether the initial distribution is stationary or not, default is TRUE.

mle.optimizer character, the MLE optimizer. Currently it is just set to "nlm".

return.code numeric, the return code from the MLE optimizer.

iterations numeric, number of iterations MLE optimizer takes.

mllk numeric, the final mllk value.

AIC numeric, the final AIC.

BIC numeric, the final BIC.

observations numeric, stores the observations post optimization

states.prob matrix, stores the state probabilities post optimization

states.local numeric, stores the local decoding states post optimization

states.global numeric, stores the global decoding states post optimization (Viterbi)

states.local.stats matrix, stores the statistics of local states post optimization

states.global.stats matrix, stores the statistics of global states post optimization

ldhmm.calc\_stats\_from\_obs

Computing the statistics for each state

### Description

This utility computes the statistics (mean, sd, kurtosis, length) for each state. It can be based on the local or global decoding result. The concept of asymptotic statistics can be applied by which the largest N observations (in absolute term) can be dropped to avoid distortion from outliers. It is assumed the object already has come with filled data in observations, states.prob, states.local, states.global slots.

### Usage

```
ldhmm.calc_stats_from_obs(object, drop = 0, use.local = TRUE)
```

```
ldhmm.drop_outliers(x, drop = 1)
```

# Arguments

object	an ldhmm object that contains the observations.
drop	numeric, an integer to drop the largest N observations, default is zero.
use.local	logical, use local decoding result, default is TURE. Otherwise, use global decod- ing result.
x	numeric, the observations.

# Value

an ldhmm object containing results of decoding, based on data

### Author(s)

Stephen H. Lihn

ldhmm.conditional\_prob

Computing the conditional probabilities

### Description

This utility computes the conditional probabilities that observation at time t equals xc, given all observations other than that at time t being the same.

# Usage

ldhmm.conditional\_prob(object, x, xc)

### Arguments

object	an ldhmm object
х	numeric, the observations.
xc	numeric, the conditional observations.

### Value

matrix of probabilities, size of xc times size of x.

### Author(s)

Stephen H. Lihn

ldhmm.decode\_stats\_history

Estimating historical statistics (mean, volatility and kurtosis)

# Description

This utility estimates historical statistics (mean, volatility and kurtosis) according to the state probabilities. The ldhmm object must have been decoded by running through ldhmm. decoding function. Note that kurtosis is naively implemented as the linear sum from each state weighted by state probabilities. It is subject to change to more rigorous formula in future releases.

# Usage

```
ldhmm.decode_stats_history(
   object,
   ma.order = 0,
   annualize = FALSE,
   days.pa = 252
)
```

### Arguments

object	a decoded ldhmm object
ma.order	a positive integer or zero, specifying order of moving average. Default is zero.
annualize	logical, to annualize the sd and mean to V ( $xsqrt(days.pa)x100$ ) and R ( $xdays.pa$ ) Default is FALSE.
days.pa	a positive integer, specifying number of days per year, default is 252.

# Value

an matrix of statistics history, size of observations times size of 3

# Author(s)

Stephen H. Lihn

ldhmm.decoding

Computing the minus log-likelihood (MLLK)

# Description

This utility computes the state probabilities, uses local and global decoding to calculate the states. The results are saved to the returned ldhmm object.

# Usage

```
ldhmm.decoding(object, x, do.global = TRUE, do.stats = TRUE)
```

# Arguments

object	an ldhmm object
х	numeric, the observations.
do.global	logical, if TRUE (default), perform Viterbi decoding.
do.stats	logical, if TRUE (default), calculate stats.

### Value

an ldhmm object containing results of decoding

# Author(s)

Stephen H. Lihn

ldhmm.df2ts

# Description

This utility converts the df input to an xts object with columns and statistics required for the fitting/plot utility in the ecd package. The require columns are Date, Close, logr. This utility can also be used to convert the input from Quandl.

# Usage

```
ldhmm.df2ts(
    df,
    date_format = "%m/%d/%Y",
    dt = "Date",
    col_in = "Close",
    col_out = "Close",
    do.logr = TRUE,
    rnd.zero = 0.01
)
```

# Arguments

df	Data.frame of the time serie
date_format	Character, date format of the input date column. It can be NULL to indicate no date conversion is needed. Default: "%m/%d/%Y".
dt	Character, the name of the input date column. Default: "Date"
col_in	Character, the name of the input closing price column. Default: "Close"
col_out	Character, the name of the output closing price column. Default: "Close"
do.logr	logical, if TRUE (default), produce xts object of logr; otherwise, just the col_out column.
rnd.zero	numeric, a small random factor (scaled to sd of logr) to avoid an unreal peak of zero log-returns.

### Value

The xts object for the time series

# Examples

## Not run:
ldhmm.df2ts(df)

## End(Not run)

ldhmm.forecast\_prob Computing the forecast probability distribution

# Description

This utility computes the forecast probability distribution (Zucchini, 5.3)

# Usage

```
ldhmm.forecast_prob(object, x, xf, h = 1)
```

# Arguments

object	an ldhmm object
x	numeric, the observations.
xf	numeric, the future observations to be forecasted.
h	integer, time steps to forecast.

### Value

matrix of probabilities, size of h times size of xf.

### Author(s)

Stephen H. Lihn

ldhmm.forecast\_state Computing the state forecast

# Description

This utility computes the state forecast, given the sequence of observations in the past.

# Usage

ldhmm.forecast\_state(object, x, h = 1)

### Arguments

object	an ldhmm object
x	numeric, the observations.
h	integer, time steps to forecast.

# Value

matrix of probabilities per state (even if h=1), number of states times size of h

# Author(s)

Stephen H. Lihn

ldhmm.forecast\_volatility

Computing the volatility forecast for next one period

# Description

This utility computes the volatility forecast based on the given future observations for next one period.

# Usage

```
ldhmm.forecast_volatility(object, x, xf, ma.order = 0, days.pa = 252)
```

# Arguments

object	an ldhmm object
x	numeric, the observations.
xf	numeric, the future observations to be forecasted.
ma.order	a positive integer or zero, specifying order of moving average. Default is zero.
days.pa	a positive integer specifying trading days per year, default is 252.

### Value

matrix of future observations and volatilities, size of 2 times length of xf.

# Author(s)

Stephen H. Lihn

ldhmm.fred\_data

### Description

This utility downloads time series from FRED. It serves as a data source for daily data, e.g. SP500 for S&P 500, and VIXCLS for CBOE VIX index. This can be concatenated to the static data to provide daily updates.

#### Usage

```
ldhmm.fred_data(symbol, col_out = "Close", do.logr = TRUE)
```

### Arguments

symbol	character, the name of the time series
col_out	character, the name of the output closing price column. Default: "Close"
do.logr	logical, if TRUE (default), produce xts object of logr; otherwise, just the col_out column. Be aware that, because logr uses diff, the first day close will be deleted.

### Value

The xts object for the time series

# Examples

```
## Not run:
ldhmm.fred_data("VIXCLS")
## End(Not run)
```

ldhmm.gamma\_init Initializing tansition probability paramter

### Description

This utility has multiple purposes. It can generate a simple transition probability matrix, using p1 and p2, if prob is left as NULL. The generated gamma is raw and not normalized. If prob is provided as a vector, the utility converts it into a matrix as gamma. Furthermore, if prob is provided as a vector or matrix, the utility applies min.gamma, and normalize the sum of t.p.m. rows to 1. This is mainly an internal function used by MLE, not be concerned by external users.

#### Usage

```
ldhmm.gamma_init(m, p1 = 0.04, p2 = 0.01, prob = NULL, min.gamma = 0)
```

### ldhmm.get\_data

#### Arguments

m	numeric, number of states
p1	numeric, the first-neighbor transition probability, default is 0.04.
p2	numeric, the second-neighbor transition probability, default is 0.01.
prob	numeric or matrix, a fully specified transition probability by user, default is NULL. If this is specified, p1, p2 would be ignored.
min.gamma	numeric, a minimum transition probability added to gamma to avoid singularity, default is 0. This is only used when prob is not NULL.

### Value

a matrix as gamma

#### Author(s)

Stephen H. Lihn

# Examples

ldhmm.get\_data Read sample data

### Description

Read sample data by specifying the symbol. The two utilities, ldhmm.get\_data and ldhmm.get\_data.arr, serves for slightly different purpose. ldhmm.get\_data works off the xts object that has two rows: the prices and log-returns indexed by the dates. ldhmm.get\_data.arr and ldhmm.get\_data.ts separate the data into list of three vectors: x is the log-return, p is the prices, and d is the dates. And allows for more sophisticated call for range of dates, and different ways of slice and lag. ldhmm.get\_data.arr takes symbol as input, while ldhmm.get\_data.ts takes an xts object.

# Usage

```
ldhmm.get_data(symbol = "dji")
ldhmm.get_data.arr(
  symbol = "dji",
  start.date = "1950-01-01",
```

```
end.date = "2015-12-31",
 on = "days",
  lag = 1,
  drop = 0,
  repeated = TRUE,
 cache = TRUE,
 do.kurtosis = FALSE
)
ldhmm.get_data.ts(
  ts,
  start.date = "1950-01-01",
 end.date = "2015-12-31",
 on = "days",
 lag = 1,
 drop = 0,
  repeated = TRUE,
 do.kurtosis = FALSE
)
```

# Arguments

symbol	character, the symbol of the time series. Default: dji
start.date, end	l.date
	Date or character of ISO format (YYYY-MM-DD), to specify the date range, default is from 1950-01-01 to 2015-12-31. Set start.date and end.date to NULL or "" if you wish to get the entire time series.
on	character, specify the calendar interval, days, weeks, months. Default is days.
lag	integer, specify the lags of return calculation, default is 1.
drop	integer, specify number of largest outliners to drop, default is 0.
repeated	logical, specify whether to use repeated sampling or unique sampling, default is TRUE. Using "repeated" sampling can reduce noise due to insufficient sample size. This is particularly useful for larger lags.
cache	logical, use R's options memory to cache xts data, default is TRUE.
do.kurtosis	logical, if specified, calculate mean, sd, var, skewness, and kurtosis, default is FALSE.
ts	xts, the time series

# Value

ldhmm.get\_data returns an xts object for the time series, with two columns - "Close" and "logr". ldhmm.get\_data.arr and ldhmm.get\_data.ts return a list of three vectors: x is the log-return, p is the prices, and d is the dates.

# Examples

dji <- ldhmm.get\_data()</pre>

18

# ldhmm.ld\_stats

```
wti <- ldhmm.get_data("wti")
spx <- ldhmm.get_data.arr("spx", lag=5)</pre>
```

ldhmm.ld\_stats Computes the theoretical statistics per state

# Description

This utility computes the statistics (mean, sd, kurtosis) based on the lambda distribution. This is used to compare to the statistics from observations for each state. alloc is a short-hand for Merton's optimal allocation, mean/sd^2.

# Usage

```
ldhmm.ld_stats(object, annualize = FALSE, days.pa = 252)
```

# Arguments

object	an ldhmm object
annualize	logical, to annaulize the sd and mean to V (xsqrt(days.pa)x100) and R (xdays.pa). Default is FALSE.
days.pa	a positive integer, specifying number of days per year, default is 252.

### Value

a matrix of statistics for each state, size of states times 4

#### Author(s)

Stephen H. Lihn

1dhmm.log\_forward Computing the log forward and backward probabilities

### Description

This utility computes the logarithms of the forward and backward probabilities, aka alpha and beta. The logarithm keeps the computation away from floating point under/over-flow. (Zucchini, 5.4)

### Usage

ldhmm.log\_forward(object, x)

ldhmm.log\_backward(object, x)

# Arguments

object	an ldhmm object
х	numeric, the observations.

# Value

numeric, the log probabilities

# Author(s)

Stephen H. Lihn

ldhmm.mle

# Computing the MLEs

# Description

Computing the MLEs using nlm package

# Usage

```
ldhmm.mle(
   object,
   x,
   min.gamma = 1e-06,
   decode = FALSE,
   plot.fn = NULL,
   plot.interval = 200,
   ssm.fn = NULL,
   print.level = 0,
   iterlim = 1000,
   ...
)
```

# Arguments

object	an ldhmm object that can supply m, param.nbr and stationary.
х	numeric, the observations.
min.gamma	numeric, a minimum transition probability added to gamma to avoid singularity, default is 1e-6.
decode	logical, run decoding after optimization, default is FALSE.
plot.fn	name of the function that takes ldhmm object. It will be called occasionally to track the progress of the fit, mainly by plotting the time series and states. E.g. When one fits the SPX index, the function ldhmm.oxford_man_plot_obs can be used to show the expected volatility vs Oxford-Man realized volatility. Default is NULL.

20

### ldhmm.mllk

plot.interval	a positive integer, specifying how often to invoke plot function, default is 200 iterations.
ssm.fn	name of the function that takes ldhmm object. This function is called after the MLLK call. The purpose is to generate an additional score for optimization. E.g. It can be used to separate the states into predefined intervals, modeling a state space model. Default is NULL.
print.level	numeric, this argument determines the level of printing which is done during the minimization process. The default value of 0 means that no printing occurs, a value of 1 means that initial and final details are printed and a value of 2 means that full tracing information is printed.
iterlim	numeric, a positive integer specifying the maximum number of iterations to be performed before the program is terminated.
	additional parameters passed to the MLE optimizer

### Value

an ldhmm object containg results of MLE optimization

# Author(s)

Stephen H. Lihn

# Examples

```
## Not run:
    param0 <- matrix(c(0.003, 0.02, 1, -0.006, 0.03, 1.3), 2, 3, byrow=TRUE)
    gamma0 <- ldhmm.gamma_init(m=2, prob=c(0.9, 0.1, 0.1, 0.9))
    h <- ldhmm(m=2, param=param0, gamma=gamma0)
    spx <- ldhmm.ts_log_rtn()
    ldhmm.mle(h, spx$x)
```

## End(Not run)

# Description

This utility computes the MLLK. It is typically invoked by the MLE optimizer. (Zucchini, 3.2)

# Usage

```
ldhmm.mllk(object, x, mllk.print.level = 0)
```

# Arguments

object	an input ldhmm object to provide static reference, such as m, param.nbr, station- ary.
х	numeric, the observations.
mllk.print.level	
	numeric, this argument determines the level of printing which is done during the minimization process. The default value of 0 means that no printing occurs, a value of 1 or greater means some tracing information is printed.

### Value

an ldhmm object containing results of MLE optimization

# Author(s)

Stephen H. Lihn

ldhmm.n2w

Transforming natural parameters to a linear working parameter array

# Description

This utility linearizes the natural parameters and transforms the contrained parameters to unconstrained parameters. (Zucchini, 3.3.1)

# Usage

```
ldhmm.n2w(object, mu.scale = 1)
```

# Arguments

object	an ldhmm object
mu.scale	numeric, if provided, e.g. $mean(abs(x))$ , it is used to scale up mu so that the scale is more friendly to the optimizer. Default is 1.

### Value

numeric, linear working parameter array

# Author(s)

Stephen H. Lihn

### Examples

```
param0 <- matrix(c(0.003, 0.02, 1, -0.006, 0.03, 1.3), 2, 3, byrow=TRUE)
gamma0 <- matrix(c(0.9, 0.1, 0.1, 0.9), 2, 2, byrow=TRUE)
d <- ldhmm(m=2, param=param0, gamma=gamma0)
v <- ldhmm.n2w(d)</pre>
```

ldhmm.plot\_spx\_vix\_obs

Plotting HMM expected volatility for SPX overlaid with adjusted VIX

# Description

This utility plots the HMM expected volatility of SPX overlaid with the VIX index adjusted by a ratio. The expected volatility is shown to have a long-term ratio of 0.79 relative to the VIX index. This plot will show how HMM deviates from VIX in a shorter time window. Optionally the insert shows the relation between the return and volatility indicated by each state. This plot is also called "volatility yield curve".

### Usage

```
ldhmm.plot_spx_vix_obs(
   object,
   days.pa = 252,
   start.date = NULL,
   end.date = NULL,
   px.origin = NULL,
   px.scale = NULL,
   vix.adj.ratio = NULL,
   insert.plot = TRUE,
   insert.viewport = NULL
)
```

#### Arguments

object	an ldhmm object with a stationary solution. If this is set to NULL, an internal 10-state HMM object will be used.
days.pa	a positive integer specifying trading days per year, default is 252.
start.date	Date or character of ISO format (YYYY-MM-DD), specifying the start date of the plot, default is NULL, which is converted to 1.5 years ago.
end.date	Date or character of ISO format (YYYY-MM-DD), specifying the end date of the plot, default is NULL, which means the latest date.
px.origin	numeric, specifying the starting value of the index price line, the default is NULL, which will start the index price line from the middle of y-axis.

px.scale	numeric, specifying the scaling factor when plotting price trend, default is 15. The closing price is converted to cumulative return by the price of the first date. Then plot from the mid-point of volatility axis with this scale.
vix.adj.ratio	numeric, if specified, VIX index is adjusted and plotted, default is NULL. Default is to use the long-term ratio between VIX and 10-state HMM, which is about 0.79.
insert.plot	logical, if true, also plot the volatility-return as insert in upper-right corner, de- fault is TRUE.
<pre>insert.viewport</pre>	
	optional viewport for the insert, default is NULL, which is internally set to grid::viewport(.8, .75, .3, .3).

# Author(s)

Stephen H. Lihn

# Examples

```
## Not run:
    ldhmm.plot_spx_vix_obs(h)
```

## End(Not run)

ldhmm.pseudo\_residuals

Computing pseudo-residuals

# Description

This utility computes pseudo-residuals. (Zucchini, 6.2)

# Usage

```
ldhmm.pseudo_residuals(object, x, xc.length = 1000)
```

# Arguments

object	an ldhmm object
х	numeric, the observations.
xc.length	a positive integer specifying the length of xc when calculating conditional prob- abilities, default is 1000.

# Value

a vector of normal quantiles

ldhmm.read\_csv\_by\_symbol

### Author(s)

Stephen H. Lihn

# Examples

```
## Not run:
    sr <- ldhmm.pseudo_residuals(object, x)
    hist(sr)
    acf(sr)
    qqnorm(sr, cex=0.5)
    L <- seq(-3,3,length.out=100)
    lines(L,L,col="red",lwd=2, lty=2)
```

## End(Not run)

ldhmm.read\_csv\_by\_symbol

Read csv file of sample data

# Description

This is a helper utility to read sample csv file into data frame. The main use for external users is to read the option data since it has a different format than other price timeseries data.

### Usage

```
ldhmm.read_csv_by_symbol(symbol = "dji", extdata_dir = NULL)
```

### Arguments

symbol	Character for the symbol of the time series. Default: dji
extdata_dir	optionally specify user's own extdata folder

### Value

The data.frame object

### Author(s)

Stephen H-T. Lihn

# Examples

dji <- ldhmm.read\_csv\_by\_symbol("dji")
spx <- ldhmm.read\_csv\_by\_symbol("spx")</pre>

ldhmm.read\_sample\_object

Read sample ldhmm object

### Description

This utility is used to read sample ldhmm object so that the user doesn't need to go through lengthy optimization process to obtain a trained HMM for advanced features.

### Usage

```
ldhmm.read_sample_object(symbol = "spx-daily-m10", extdata_dir = NULL)
```

#### Arguments

symbol	Character for the symbol of the time series. Default is spx-daily-m10
extdata_dir	optionally specify user's own extdata folder

#### Value

The ldhmm object

#### Author(s)

Stephen H-T. Lihn

# Examples

hs <- ldhmm.read\_sample\_object() # SPX daily 10-state HMM</pre>

ldhmm.simulate\_abs\_acf

Simulating auto-correlation (ACF)

#### Description

This utility simulates the auto-correlation. The first few lag of ACF should match the ACF from the market data fairly well. This is a major validation of a successful HMM. Be aware this is a CPU intensive calculation. It uses the multi-core functionality.

### Usage

```
ldhmm.simulate_abs_acf(object, n = 10000, lag.max = 5, debug = FALSE)
```

### Arguments

object	an ldhmm object that can supply m, param.nbr and stationary.
n	a positive integer specifying number of observations to simulate.
lag.max	a positive integer, specifying number of lags to be computed.
debug	logical, specifying to print progress message or not. Default is FALSE.

# Value

a vector of ACF

### Author(s)

Stephen H. Lihn

ldhmm.simulate\_state\_transition
 Simulating state transition

# Description

This utility allows to simulate the states and obervations over time. Be aware this is a CPU intensive calculation. It uses the multi-core functionality.

### Usage

ldhmm.simulate\_state\_transition(object, init = NULL)

### Arguments

object	an ldhmm object that can supply m, param.nbr and stationary.
init	a positive integer specifying number of observations to simulate initially. The default is NULL, indicating that the simulation should use the (local) states and observations from within the object, and simulate the next set of random states and observations according to gamma. When init is an integer, the utility will generate random states and observations according to delta.

#### Value

an ldhmm object containing the simulated states and observations. The observations are stored in the observations slot. The states are stored in the states.local slot.

# Author(s)

Stephen H. Lihn

ldhmm.sma

# Description

This utility calculates simple moving average, with option to backfill for NA.

# Usage

```
ldhmm.sma(x, order, na.backfill = TRUE)
```

# Arguments

х	numeric, the time series.
order	a positive integer to specify order of moving average.
na.backfill	logical, specify whether to backfill for NA. Default is TRUE.

# Value

numeric, simple moving average, same length as x.

### Author(s)

Stephen H. Lihn

### Examples

```
x <- 1:100
a <- ldhmm.sma(x, 10)
```

ldhmm.state\_ld Constructing the ecld objects per state

### Description

This utility constructs the ecld objects per state and return them in a list of easy query.

# Usage

ldhmm.state\_ld(object, state = NULL)

# Arguments

object	an ldhmm object
state	numeric, the states.

# ldhmm.state\_pdf

### Value

a list of ecld objects

# Author(s)

Stephen H. Lihn

1dhmm.state\_pdf Computing the PDF per state given the observations

### Description

Computing the PDF per state given the observations. Only one of state or x can be a vector per call.

# Usage

```
ldhmm.state_pdf(object, state, x)
```

### Arguments

object	an ldhmm object
state	numeric, the states.
x	numeric, the observations

### Value

a vector or matrix of PDF. The dimension of matrix is state times x

### Author(s)

Stephen H. Lihn

ldhmm.ts\_abs\_acf Computing ACF of the absolute value of a time series

# Description

This utility computes the ACF of the absolute value of a time series as a proxy of the auto-correlation of the volatility. It allows to drop the largest N outliers so that they would not skew the ACF calculation.

### Usage

ldhmm.ts\_abs\_acf(x, drop = 0, lag.max = 100)

### Arguments

х	numeric, the observations.
drop	a positive integer, specifying number of outliers to be dropped.
lag.max	a positive integer, specifying number of lags to be computed.

# Value

a vector of ACF

# Author(s)

Stephen H. Lihn

ldhmm.ts\_log\_rtn Get log-returns from historic prices of an index

# Description

This utility returns the dates and log-returns of an index available in the package. Note that the data is static. A limited set of live daily time series can be appended from FRED, e.g. SPX, VIX, DJIA.

# Usage

```
ldhmm.ts_log_rtn(
   symbol = "spx",
   start.date = "1950-01-01",
   end.date = "2015-12-31",
   on = "weeks",
   fred.data = FALSE
)
```

# Arguments

symbol	character, specify the symbol of the index, default is spx. If fred.data is true, the program can infer FRED symbol as upper case of symbol.
start.date, end	.date
	Date or character of ISO format (YYYY-MM-DD), to specify the date range, default is from 1950-01-01 to 2015-12-31. Set start.date and end.date to NULL or "" if you wish to get the entire time series.
on	character, specify the interval, days, weeks, months. Default is weeks.
fred.data	logical, specify whether to append daily time series data from FRED, default is FALSE.

### Value

list of three vectors: d is the dates and x is log-returns and p is prices

### ldhmm.viterbi

### Author(s)

Stephen H. Lihn

### Examples

a <- ldhmm.ts\_log\_rtn()</pre>

1dhmm.viterbi Computing the global decoding by the Viterbi algorithm

# Description

This utility computes the global decoding by the Viterbi algorithm.

# Usage

ldhmm.viterbi(object, x)

# Arguments

object	an ldhmm object
х	numeric, the observations.

### Value

a vector of states

# Author(s)

Stephen H. Lihn

ldhmm.w2n

Transforming working parameter array to natural parameters

# Description

This utility transforms the working parameter array back to the vectors and matrix of the contrained parameters. (Zucchini, 3.3.1)

# Usage

```
ldhmm.w2n(object, par.vector, mu.scale = 1)
```

# Arguments

object	an ldhmm object that can supply m, param.nbr and stationary.
par.vector	numeric, linear working parameter array. See ldhmm.n2w.
mu.scale	numeric, it should mirror what is provided to ldhmm.n2w. Default is 1.

# Value

an ldhmm object

# Author(s)

Stephen H. Lihn

numericOrNull-class The numericOrNull class

# Description

The S4 class union of numeric and NULL, primarily used for detla
